# Human Ingestion of Bacillus Anthracis-Contaminated Meat — Minnesota, August 2000

On August 25, 2000, the Minnesota Department of Health (MDH) was notified by the Minnesota Board of Animal Health (MBAH) of *Bacillus anthracis* isolated from a steer on a farm in Roseau County, Minnesota. The infected steer was one of five dead cattle found in a pasture on August 20. On the basis of phage typing of isolates cultured from tissues and blood samples by the North Dakota State University Veterinary Diagnostic Laboratory, *B. anthracis* was confirmed. This report describes the management of and public health response to human exposure to meat contaminated with anthrax.

On July 24, the farmer who owned the infected steer also had killed, gutted, and skinned a cow that was unable to rise. A local veterinarian approved the slaughter of the cow for consumption by the farmer's family. Immediately after slaughter, the farmer took the carcass (carcass X) to a custom meat-processing plant; on July 31 and August 1, carcass X was processed. Two family members ate hamburgers made from carcass X on August 15 and steaks on August 19; three other family members ate hamburgers on August 20. A sixth member prepared the meals and also may have eaten contaminated meat. All meat was reported to have been well cooked. To investigate the possibility that they had eaten contaminated meat, the family members were interviewed by MDH on August 25. Two reported gastrointestinal illness; one reported 1 day of diarrhea approximately 48 hours after eating meat from carcass X, and the second reported 3 days of abdominal pain, diarrhea, and a temperature of 102.3 F (39.1 C) beginning 24–36 hours after consumption. Both recovered without treatment. The family was advised by MDH not to eat any more of the meat, to contact a physician, and to begin antibiotic prophylaxis with ciprofloxacin (500 mg, orally, twice daily).

On August 29, samples of carcass X tested by the MDH Public Health Laboratory (MDH PHL) were found to contain gram-positive bacilli on microscopic examination. *B. anthracis* contamination was confirmed at MDH PHL and the U.S. Army Medical Research Institute for Infectious Diseases through culture on blood agar, presence of a capsule, lack of motility, gamma-phage test, and fluorescent antibody to cell wall polysaccharide and capsular antigens. On the basis of this exposure to meat highly contaminated with *B. anthracis*, the family was advised to continue chemoprophylaxis, and vaccination with anthrax vaccine was initiated (Anthrax Vaccine Adsorbed\*, Bioport Corporation, Lansing, Michigan).

Bacillus Anthracis — Continued

The Minnesota Department of Agriculture (MDA) contacted the custom meat processing plant on August 28 and placed a hold on all meat processed after carcass X. On August 29, MDA inspected the plant; sanitation practices were satisfactory. Seven carcasses had been processed after carcass X. Owners of meat from the carcasses were advised not to eat any of the meat and were asked to return meat to a central location for incineration; all the meat products were accounted for and none had left Minnesota. Samples from the other carcasses and environmental swabs collected after plant cleaning tested negative for *B. anthracis*.

T Lewis, A Friedlander, MD, H Heine, PhD, R Culpepper, MD, E Henchal, PhD, G Ludwig, PhD, C Rossi, MS, J Teska, PhD, J Ezzell, PhD, E Eitzen, MD, US Army Medical Research Institute for Infectious Diseases. Food Safety and Inspection Svc, Animal and Plant Health Inspection Svc, US Dept of Agriculture. Epidemiology Program Office, Meningitis and Special Pathogens Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and an EIS Officer, CDC.

**Editorial Note:** Anthrax is a zoonotic disease caused by the spore-forming bacterium *B. anthracis*. Human disease usually occurs through cutaneous exposure to infected animal tissue or products. Rarely, inhalation or ingestion of *B. anthracis* spores also leads to anthrax. In the United States during the early part of the 20th century, approximately 130 human cases occurred annually (1); two cutaneous infections have been reported since 1992.

Before this exposure, no animal anthrax cases had been reported in northern Minnesota since recordkeeping began in 1909. However, in adjacent areas of North Dakota during 2000, 120–150 cattle have died of anthrax (L. Schuler, North Dakota state veterinarian, personal communication, 2000), and 11 farms have reported anthrax-related cattle deaths in nearby Manitoba, Canada (Figure 1) (J.G. Spearman, Manitoba Department of Agriculture, personal communication, 2000).

Gastrointestinal anthrax in humans occurs 1–7 days after eating raw or undercooked meat from infected animals (2), and two forms of gastrointestinal disease have been reported (3). Disease affecting the distal gastrointestinal tract results in nausea, anorexia, and fever followed by abdominal pain and bloody stool. The case fatality rate among reported cases ranges from 25%–60% (2). Gastrointestinal anthrax never has been documented in the United States because livestock are vaccinated for anthrax in areas where the disease is endemic; animals routinely are inspected by federal and state meat inspectors before, during, and after slaughter; and raw meat is eaten infrequently. Anthrax has not been documented among the persons exposed to *B. anthracis*-contaminated meat described in this report; however, a serologic test to determine presence of infection is pending.

Limited experience with gastrointestinal anthrax complicates recommendations for use of postexposure prophylaxis. An extended duration of therapy is recommended for inhalational exposure because of the persistence of spores resistant to the action of antimicrobial agents (4,5). Upon cessation of chemoprophylaxis, such spores can cause disease several weeks after exposure. No evidence supports the existence of persistent spores associated with gastrointestinal forms of the disease; however, the meat consumed by the family in this report was highly contaminated with *B. anthracis*. Although

Bacillus Anthracis — Continued

FIGURE 1. Location where *Bacillus anthracis* has been isolated from steer carcasses — Roseau County, Minnesota, North Dakota, and Manitoba, Canada, 2000

possible interventions range from close observation to antibiotics alone to antibiotics with vaccination, because the family was at high risk for anthrax infection, management consisted of an extended course of ciprofloxacin combined with administration of anthrax vaccine.

Federal-inspected and state-inspected animal processing facilities are required to perform intensive cleaning after contact with an anthrax-infected carcasses<sup>†</sup>; veterinary inspection is not provided at custom meat processors. Slaughter house workers who may be exposed to an anthrax-contaminated carcass should receive medical evaluation for symptoms and for possible treatment. Management of anthrax in livestock should include 1) quarantine of the herd; 2) removal of the herd from the contaminated pasture, if possible; 3) vaccination of healthy livestock; 4) treatment of symptomatic livestock; and 5) disposal of infected carcasses, preferably by burning. Bedding and other material found around the carcass (e.g., soil) should be incinerated with the carcass and buried (6).

Veterinarians notified of sudden death in an animal or of an animal unable to rise should consider anthrax as a diagnosis, especially in areas where anthrax is endemic (6). However the potential risk for animal anthrax exists in all areas of the United States.

<sup>&</sup>lt;sup>†</sup>9 CFR Part 310.9 (2000).

Bacillus Anthracis — Continued

Vaccination of livestock in areas where anthrax is endemic is the most effective method of prevention in animals and humans. Cases of anthrax in animals and cases of suspected human exposure should be reported immediately to the state health department, federal animal heath officials, and to CDC's National Center for Infectious Diseases, Meningitis and Special Pathogens Branch, telephone (404) 639-3158.

# Public Health Dispatch

# Outbreak of Acute Febrile Illness Among Participants in EcoChallenge Sabah 2000 — Malaysia, 2000

On September 7, 2000, CDC was notified by Idaho Department of Health about a case of acute febrile illness in a 35-year-old man; the illness was characterized by acute onset of high fever, chills, headache, and myalgias. The patient had participated in the EcoChallenge Sabah 2000 Expedition Race, a multisport event held during August 20–September 3, at various sites in Sabah in Malaysian Borneo.

This report presents preliminary findings of an ongoing investigation to identify cases of acute febrile illness among athletes who participated in the EcoChallenge Race in Borneo during August 2000. Preliminary laboratory test results indicate the probable cause of illness to be leptospirosis, a spirochete infection. The event involved jungle trekking, open water swimming, river and ocean paddling, mountain biking, canyoneering, scuba diving, and spelunking. Participating were 76 four-person teams from 26 countries, including 37 teams from the United States. Subsequently, nine other EcoChallenge participants who became ill were identified in California (five in San Diego County, two in Orange County, and two in Los Angeles). To identify additional athletes with febrile illness, an EcoChallenge participant list was obtained from race organizers, and a telephone survey was administered by CDC with the assistance of several state public health departments. As of September 13, 82 (53%) of 155 U.S.-based athletes have been contacted; 37 (45%) reported having fever and 12 (15%) were hospitalized. No deaths have been reported.

Acute Febrile Illness — Continued

On September 12, serum specimens obtained from two hospitalized athletes from Los Angeles were tested at CDC for leptospirosis using the Dip-S-Ticks\* assay (Leptospira INDX Dip-S-Ticks; Integrated Diagnostics, Baltimore, Maryland) and the Pan-Bio\* enzyme-linked immunosorbent assay (ELISA) IgM test (PanBio, Brisbane, Australia). One athlete tested positive with both tests on an acute-phase serum specimen obtained 4 days following onset of fever. The second athlete tested negative with both tests on the acute-phase specimen but positive with both tests on a follow-up specimen obtained 4 and 6 days following onset of fever.

On the basis of laboratory test results and the clinical features of illness, CDC advises the following to clinicians caring for EcoChallenge participants. First, asymptomatic athletes that were taking chemoprophylaxis for leptospirosis (i.e., 200 mg oral doxycycline weekly) should ensure that their final weekly dose was taken following completion of the race (1). Second, although the merits of one dose of postexposure chemoprophylaxis with 200 mg oral doxycycline are unknown, asymptomatic athletes who participated in the race and who were not taking chemoprophylaxis for leptospirosis may wish to discuss the single-dose option with their physician. Third, for athletes with mild symptoms consistent with leptospirosis, treatment should include 7 days of oral doxycycline, 100 mg twice daily (2). Finally, for hospitalized patients with severe illness (e.g., persistent high-grade fever, impaired hepatic or renal function, or severe neurologic disturbances, including coma, hemiplegia, or transverse myelitis), treatment should include 7 days of intravenous penicillin G, 1.5 million units every 6 hours (3). As with other spirochete infections, a Jarisch-Herxheimer reaction can develop following the initiation of penicillin therapy for leptospirosis (4). Although these reactions serve as an indicator of therapeutic efficacy, they can be associated with increased morbidity and mortality; patients receiving intravenous penicillin should be monitored for shocklike symptoms.

On September 13, CDC issued an advisory (http://webdev.cdc.gov/travel/other/lepto-malaysia.htm) about the probable leptospirosis outbreak associated with the EcoChallenge event to raise awareness among health-care workers and participants of the event in Borneo. The Meningitis and Special Pathogens Branch (MSPB) at CDC is interested in receiving reports through state and local health departments of additional participants who have been ill or have had fever since August 21. In addition, MSPB will test clinical specimens for leptospirosis received through state and local health departments.

# Screening With the Prostate-Specific Antigen Test — Texas, 1997

Prostate cancer is the second leading cause of cancer-related deaths among men in Texas (1). From 1990 to 1997, the average annual number of prostate cancer-related deaths in Texas was 1900, and the average annual death rate was 20.9 per 100,000 population (1). An estimated 10,186 new prostate cancer cases will occur in 2000 in Texas (2). Several screening methods are available for early detection of prostate cancer, including digital rectal exam, transrectal ultrasound, and prostate-specific antigen (PSA) testing, which involves a simple phlebotomy (3). To assess the proportion of men in Texas receiving PSA testing and to identify factors associated with receipt of this testing, the Texas Department of Health added three questions to its 1997 Behavioral Risk Factor Surveillance System (BRFSS) survey relating to PSA testing. This report summarizes this analysis and indicates that approximately 37% of men aged ≥40 years had received PSA testing and that receipt of PSA testing was associated with a doctor's recommendation.

BRFSS is a state-based, random-digit—dialed telephone survey of the civilian, noninstitutionalized U.S. population aged ≥18 years. In 1997, men aged ≥40 years who responded to the Texas BRFSS were asked, "Have you heard about the PSA blood test?", "Have you ever been told by a doctor that you should have a PSA blood test?", and "Have you ever had a PSA blood test?" Responses were weighted to provide statewide estimates; standard errors and 95% confidence intervals (CIs) were calculated, and univariate and multivatiate analyses were performed using SUDAAN.

Among respondents, 60% (95% Cl=55%–65%) said they had heard of the PSA test. Of those who had heard of the test, 52% (95% Cl=45%–59%) were told by their doctor that they should receive the test. Of those who had heard of the test and whose doctor recommended it, 91% (95% Cl=85%–96%) reported having received the test. Overall, 37% (95% Cl=32%–42%) of men received the PSA test, representing approximately 62% of men who had heard of the test. Of those who were not told by a doctor to have the test, 24% (95% Cl=14%–30%) received the test.

Univariate analysis indicated that receiving the PSA test was associated with a doctor's recommendation (odds ratio [OR]=28.2; 95 Cl=13.3–59.8) (Table 1). Other factors associated with receiving the test were having had a physical examination during the preceding 2 years (OR=5.4; 95 Cl=2.6–11.0), being aged  $\geq$ 50 years (OR=5.2; 95 Cl=5.1–5.2), being covered by a health plan (OR=3.8; 95 Cl=2.0–7.1), having ever received a proctoscopic examination (OR=3.4; 95 Cl=2.0–5.7), being non-Hispanic (OR=2.2; 95 Cl=2.2–2.3), and having  $\geq$ 16 years of education (OR=1.9; 95 Cl=1.2–3.0). Logistic regression analysis indicated that receiving a PSA test was associated with a doctor's recommendation (adjusted OR=80.4; 95% Cl=21.4–301.9), and being aged >50 years (adjusted OR=4.0; 95% Cl=1.3–12.3).

Reported by: K Condon, Behavioral Risk Factor Surveillance System Program, L Suarez, PhD, Office of the Associate Commissioner of Disease Control and Prevention, D Perrotta, PhD, State Epidemiologist, Texas Dept of Health. Epidemiology and Health Svcs Research Br, Div of Cancer Prevention and Control, National Center for Chronic Disease Prevention and Health Promotion; State Br, Div of Applied Public Health Training, Epidemiology Program Office; and an EIS Officer, CDC.

**Editorial Note**: The findings in this report document a strong association between a doctor's recommendation and receipt of a PSA test, indicating that physician advice is a key determinant of whether men are tested. In Texas, approximately 60% of men who had heard of PSA testing reported receiving the test. Nearly all of the men whose doctor recommended the PSA test took that advice.

<sup>\*</sup> Confidence interval.

Prostate cancer screening recommendations differ among national organizations. The American Cancer Society (ACS) recommends that men aged  $\geq 50$  years who receive an annual examination be offered the Digital Rectal Examination and the PSA test (4). ACS also recommends that men aged  $\geq 40$  years be informed about the risk for prostate cancer (5). In comparison, because no evidence exists that early detection and treatment influences the overall death rate from this disease and about half of the men who undergo surgical treatment of localized lesions experience side effects (e.g., incontinence and impotence) (6), the U.S. Preventive Services Task Force, the American College of Physicians, the American Society of Internal Medicine, the National Cancer Institute, the American Association of Family Practitioners, and the American College of Preventive Medicine do not advocate routine screening (7,8). Despite the conflicting recommendations, PSA testing has increased rapidly among asymptomatic men in the United States (9).

The findings in this report are subject to at least four limitations. First, BRFSS questions did not distinguish prostate cancer screening from diagnostic testing. Some respondents may have received PSA testing as part of a diagnostic evaluation for symptoms or to monitor treatment for existing prostate cancer. Second, respondents may have had the PSA test performed, but did not know that it had been done. Third, among men for whom PSA testing was not recommended, it is not possible to distinguish men whose physicians discouraged screening from those whose physicians did not mention screening. Finally, because the survey did not ask men how they heard about the test, the proportion of men hearing about the test from sources other than their doctor is not known.

The findings of this report suggest that interest in prostate cancer and awareness about the available screening tests for this disease is substantial. These data are consistent with information from other studies that indicate a substantial proportion of men aged >40 years have received PSA testing. Because PSA testing potentially can have an

<sup>&</sup>lt;sup>†</sup> Factors included in the logistic regression analysis model for the adjusted odds ratio were told to receive a PSA, ever had a proctoscopic examination, race, age, education level, marital status, having a family member diagnosed with prostate cancer, having a health plan, having a checkup during the preceding 2 years, income, prevented from seeking medical care because of cost, and Hispanic ethnicity.

Prostate-Specific Antigen Test — Continued

impact on statistics about prostate cancer incidence and outcomes, ongoing surveillance of the trends and determinants of the use of this procedure are warranted (8). As a result, CDC is incorporating questions about PSA testing in the 2001 BRFSS for every state. This effort, and continuing surveillance in states such as Texas, will provide information on the use of prostate cancer testing and facilitate a clearer delineation of the public health impact of this screening.

Although prostate cancer screening recommendations vary, one consistent element is that physicians should counsel patients about the risks for and potential benefits of treatment for early prostate cancer so that patients can participate in the decision making about whether to be screened. To counsel patients effectively about the risks for and benefits of treatment of early prostate cancer, physicians need access to current information and to incorporate it into their practices.

## Update: West Nile Virus Activity — Northeastern United States, 2000

Surveillance data reported to CDC indicate intensified transmission and geographic expansion of the West Nile Virus (WNV) outbreak in the northeastern United States. Increasing reports of WNV infections in American crows, other avian species, and mosquitoes are being accompanied by reports of neurologic disease caused by WNV in humans, horses, and other mammals. This report updates human data through September 12 and animal data through September 8, 2000.

Since July 20, 12 persons have been hospitalized with serious central nervous system infections caused by WNV; eight had encephalitis, and four had meningitis. Patients ranged in age from 40 to 87 years; seven were men. Eight resided in Richmond County (Staten Island), New York, two in Kings County (Brooklyn), New York, and one in Hudson County, New Jersey. One person spent substantial time both in Brooklyn, New York, and Bergen County, New Jersey. Diagnoses were confirmed by ELISA for WNV-specific IgM

West Nile Virus — Continued

in cerebrospinal fluid. Subsequently, a four-fold rise in plaque-reduction neutralization antibody titer was demonstrated in four of these patients. Nine patients improved and were discharged from the hospital; three remain hospitalized.

Surveillance detected epizootic activity (15 WNV-infected dead birds and five infected mosquito pools in Staten Island; 10 infected dead birds in Hudson County; and two infected dead birds and one infected live hatch-year bird in Brooklyn) before onset of human illness on July 20 (first Staten Island case), August 6 (Hudson County), and August 15 (first Brooklyn case). The most recent onset of human illness was September 2.

Veterinary surveillance has detected WNV infection in five horses with severe neuro-logic disease (one horse each in Middlesex County, Massachusetts; Atlantic and Cape May counties, New Jersey; Staten Island, New York; and Washington County, Rhode Island). Onset of illness in these horses ranged from August 17 to 29. WNV infection has been confirmed in six bats (four live big brown bats [*Eptesicus fuscus*] from Albany County, New York, and two dead little brown bats [*Myotis lucifugus*] from Ontario County, New York) that originally were submitted for rabies testing. WNV infection was confirmed in a dead raccoon from New York County (Manhattan) that was found on August 19.

Mosquito surveillance has detected WNV in 237 mosquito pools in 15 counties in four states (223 pools in New York, eight in New Jersey, and three each in Connecticut and Massachusetts); 84 (36%) were from Staten Island. Of the 237 reported WNV-infected pools, 137 pools were *Culex pipiens/restuans*, 44 were *Culex pipiens*, 25 were *Culex salinarius* (23 from Staten Island, one from Bronx, and one from Queens, New York City), three were *Culex restuans*, three were *Aedes japonicus* (Orange, Rockland, and Westchester counties, New York), three were *Aedes vexans* (Brooklyn and Staten Island), two were *Aedes triseriatus* (Staten Island), and one was *Anopheles punctipennis* (Staten Island).

Avian surveillance has identified 1471 WNV-infected dead birds from 79 counties in six states (586 birds in New Jersey, 536 in New York, 241 in Connecticut, 103 in Massachusetts, four in Rhode Island, and one in New Hampshire). Since 1999, WNV has been identified in 56 avian species in the United States, 48 of which are native. In New York state, all types of submitted avian species are tested for WNV; of the 536 birds infected with WNV in 2000, 347 (65%) were American crows, 82 (15%) were blue jays, and 107 (20%) were other species. WNV antibody was documented in a serologic specimen collected August 4 from a previously seronegative sentinel chicken in Westchester County, New York.

Reported by: A Novello, MD, D White, PhD, L Kramer, PhD, C Trimarchi, MS, M Eidson, DVM, D Morse, MD, B Wallace, MD, P Smith, MD, State Epidemiologist, New York State Dept of Health; W Stone, MS, Dept of Environmental Conservation, Albany; B Cherry, VMD, PhD, B Edwin, J Kellachan, MPH, V Kulasekera, PhD, J Miller, MD, New York City Dept of Health. Arbovirus Diseases Br, Div of Vector Borne Infectious Diseases, National Center for Infectious Diseases; and ElS officers, CDC.

**Editorial Note:** WNV primarily circulates between birds and mosquitoes and probably only incidentally infects humans, horses, and other mammals. As a result, WNV activity in birds and mosquitoes in a specific area generally precedes WNV infection in humans

West Nile Virus — Continued

and horses (1). In 2000, the WNV surveillance system documented epizootic WNV infections in birds and mosquitoes as sentinel events before reports of severe neurologic WNV infection in humans and prompted immediate implementation of mosquito control. This confirms the pattern suspected in 1999 when an epizootic among American crows preceded the outbreak of 62 humans identified with WNV encephalitis and meningitis in the New York City metropolitan area (2).

Many counties with intense WNV activity in mosquito and avian populations during the summer of 2000 have not reported WNV infections in humans or other mammals. This is probably a result of a combination of intensive mosquito control activities and variable mosquito feeding behaviors, reservoir host behaviors, human outdoor activities, and use of protective measures. However, the 12 patients with severe central nervous system disease caused by WNV probably represent a small proportion of humans infected with WNV this season. Not all persons with neurologic WNV infection may have had the condition diagnosed or reported. Most persons with WNV infection are asymptomatic or have only nonspecific symptoms for which WNV testing is not performed routinely. A serosurvey in Queens, New York City, after the 1999 outbreak indicated that <1% of WNV-infected persons developed severe neurologic disease.

Health-care providers in areas with documented epizootic activity should consider WNV infection in persons with suspected viral meningitis (especially among adults) or encephalitis (regardless of age). Although severe WNV central nervous system disease may be more common in the elderly, eight of the 12 persons in this report were aged <65 years. In the 1999 WNV outbreak in the New York City area, the youngest patient was aged 5 years. WNV and other arboviruses (Eastern equine encephalitis, St. Louis encephalitis, and California serogroup viruses) can cause disease in the northeastern United States through the end of October and later in more southern locations.

The recent diagnosis of a WNV-infected horse in southern New Jersey (Cape May County), a major stopover for birds migrating south, underscores the need for enhanced avian morbidity and mortality surveillance in areas south of New York City and New Jersey. If ongoing local WNV epizootic activity is detected, public health measures should be enhanced to reduce the risk for human infection (3).

N: Not notifiable. U: Unavailable. -: No reported cases. C.N.M.I.: Commonwealth of Northern Mariana Islands.

\*Individual cases can be reported through both the National Electronic Telecommunications System for Surveillance (NETSS) and the Public Health Laboratory Information System (PHLIS).

† Chlamydia refers to genital infections caused by *C. trachomatis*. Totals reported to the Division of STD Prevention, NCHSTP.

† Updated monthly from reports to the Division of HIV/AIDS Prevention — Surveillance and Epidemiology, National Center for HIV, STD, and TB Prevention. Last update August 27, 2000.

U: Unavailable. -:No reported cases.

\*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of ≥100,000. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included. Pneumonia and influenza.

\*Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.

\*Total includes unknown ages.

## Notice to Readers

## **Satellite Broadcast on HIV Prevention**

"HIV Prevention Update: Men Who Have Sex With Men," a satellite broadcast, is scheduled for Thursday, November 30, 2000, at 1–3 p.m. eastern standard time. CDC and the Public Health Training Network are sponsoring this forum, which will focus on activities and resources to prevent human immunodeficiency virus (HIV) infection among men who have sex with men (MSM). Viewers will hear about CDC activities and programs occurring throughout the country.

This broadcast is designed for organizations and persons who provide HIV prevention and other health and social services for MSM. This audience includes public health programs, community-based organizations, and policymakers. Speakers will discuss the HIV epidemic among MSM, factors contributing to increases in risk behaviors, effective HIV prevention programs for MSM, and resources and technical assistance for conducting HIV prevention programs for this population. Viewers can fax questions and comments before and during the broadcast.

Additional information for organizations and potential viewers is available through the World-Wide Web site for the broadcast, http://www.cdcnpin.org/broadcast, and CDC's Fax Information System, telephone (888) 232-3299, by entering document number 130030 and a return fax number. Organizations setting up viewing sites are encouraged to register online or by fax as early as possible so that viewers may access information about viewing locations when visiting the web site or calling the information line.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/mmwr or from CDC's file transfer protocol server at ftp://ftp.cdc.gov/pub/Publications/mmwr. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333: telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.
