Social Security Administration  
Office of the Actuary

October 1985  
SSA Pub. No. 11-11542

## FOREWORD

Actuarial Study No. 95 describes the population projections that underlie the long-range cost estimates for the Old-Age, Survivors, and Disability Insurance System, which are included in the 1985 Report of the OASDI Board of Trustees to Congress.

The reader should be aware that the population projections differ from those published by the Bureau of the Census. The projections prepared by the Bureau of the Census are generally for only the United States including armed forces overseas. Those prepared by the Office of the Actuary also include Puerto Rico, Guam, American Samoa, the Virgin Islands, and other U.S. citizens living abroad. In addition, the assumptions used by the Bureau of the Census in making population projections are not exactly the same as the assumptions used by the Office of the Actuary.

The reader should also be aware that the historical populations presented in this study include varying geographical regions and population subgroups and, therefore, may not be consistent with one another.

Francisco R. Bayo  
Deputy Chief Actuary

## A. INTRODUCTION

Each year estimates of future income and expenditures of the Old-Age and Survivors Insurance and Disability Insurance (OASDI) program are presented to the Congress in the Annual Report of the Board of Trustees. These estimates provide fundamental financial guidelines in the policy making process for OASDI.

The initial step in the estimating process is to project the number of people in the geographical areas covered by OASDI for each of the next 75 years. This study provides further details about the population projections used in preparing the 1985 Annual Report of the OASDI Board of Trustees. The population projections were also used in estimating the future financial status of the Hospital Insurance (HI) program as described in the 1985 Annual Report of the HI Board of Trustees. The population projections described in this study supersede those published in Actuarial Study Number 92, which were used in the preparation of the 1984 Annual Reports. These new projections start from the July 1, 1983 population; reflect more recent data on fertility, mortality, marriage, and divorce; and revise the projections of mortality, fertility, net immigration, divorce, and marriage. Considerably more detail than is published here is available from the Office of the Actuary, upon request.

Because eligibility for many categories of OASDI benefits depends on marital status, the population is projected by marital status, as well as by age and sex. The projections start from a recent estimate of the population in the Social Security Area by age, sex, and marital status and from a recent estimate of existing marriages by age of husband and age of wife. Three separate projections, denoted Alternatives I, II, and III, are developed by analyzing historical data and making three different sets of assumptions about future net immigration, birth rates and death rates.

Alternative II, also referred to as the intermediate projection, is based on assumptions that are thought to be the most likely to occur among the three sets presented. Alternative I is designated as optimistic since among the three projections the assumptions selected produce the most favorable financial effect for OASDI. Conversely, the assumptions chosen for Alternative III, designated pessimistic, produce the most unfavorable financial effect. Alternatives I and III are designed to give policy makers a sense of the variability inherent in the financial projections.

## B. STARTING POPULATION

The starting population for the projections was the estimated population in the Social Security Area as of July 1, 1983, by single year of age, sex, and marital status. The components of the Social Security Area and the estimated population of each component (in thousands) are as follows:

|   |         |
|---|---------|
| Residents of the fifty States and D.C.                            |         |
| and armed forces overseas.....                                    | 234,496 |
| Adjustment for net census undercount.....                         | 3,985   |
| Civilian residents of Puerto Rico.....                            | 3,262   |
| Civilian residents of the Virgin Islands.....                     | 104     |
| Civilian residents of Guam.....                                   | 108     |
| Civilian residents of American Samoa.....                         | 35      |
| Federal civilian employees overseas.....                          | 42      |
| Dependents of Armed Forces and Federal employees<br>overseas..... | 508     |
| Crew members of merchant vessels.....                             | 15      |
| Other citizens overseas.....                                      | 511     |
| Total.....  | 243,066 |

The estimate of the number of residents of the fifty States and D.C. and Armed Forces overseas by sex for single years of age through 84, and the age group 85 and over as of July 1, 1983, was obtained from Current Population Reports, Series P-25, No. 949, published by the Bureau of the Census. The numbers of persons in the other components of the Social Security Area were estimated by sex for single years of age through 84, and the age group 85 and over from data of varying detail. The latest unpublished Bureau of the Census estimates of the net 1980 census undercount assuming 3.5 million illegal immigrants were used in determining the adjustment for net census undercount. The numbers of civilian residents of Puerto Rico, the Virgin Islands, Guam, and American Samoa were estimated from data obtained from the Bureau of the Census. The numbers of Federal civilian employees and of armed forces overseas were estimated from data supplied by the State Department. The number of crew members of merchant vessels was estimated from data obtained from the Maritime Administration. The number of other citizens overseas covered by Social Security was estimated from data supplied by the State Department. The overlap among the components, believed to be small, was ignored. The age distribution of those aged 85 and over in the starting population was assumed to be the same as that in the population enrolled under the Medicare program as of January 1, 1983.

The distribution of the starting population by marital status (never married, currently married, currently widowed, and currently divorced) was estimated by age and sex from data published by the Bureau of the Census in Current Population Reports, Series P-20, No. 389. A distribution of starting married population by age of husband crossed with age of wife was estimated from data published by the Bureau of the Census in the 1970 Census of Population Subject Report on Marital Status No. PC(2)-4C. The distribution as shown in the 1970 census was adjusted to represent 1983 by

an iterative proration method designed to assure consistency with the previously estimated starting married population by age and sex. Table 1 shows the starting population in the Social Security Area by age group, sex, and marital status. Table 2 shows the starting married population by age group of husband crossed with age group of wife.

## C. ANALYSIS AND PROJECTION OF COMPONENTS OF POPULATION CHANGE

In attempting to estimate net immigration and numbers of births, deaths, marriages, and divorces in future years, it is instructive to review and analyze historical trends. Since the actual numbers of births, deaths, marriages, and divorces depend on the size of the population, it is better to analyze them as rates rather than as absolute numbers. A rate is defined as the ratio of the number of occurrences of an event during a year to the mid-year population having the potential to experience the event. Because death rates vary significantly by sex, they are calculated for males and females separately. Because rates of birth, death, marriage, and divorce vary greatly by age, they are calculated on an age-specific basis (each age or age group separately) rather than on a crude basis (all ages combined). Although calculating the rates on an age-specific basis improves accuracy, it also yields an over-abundance of figures for any one year. Thus in order to study trends through time, it becomes helpful, if not necessary, to use a single statistic that summarizes the age-specific rates for each year.

### 1. Fertility

Age-specific birth rates are defined as the births during the year to mothers at the specified age divided by the mid-year female population at that age. Birth rates for women at each age 14 through 49 were obtained from the National Center for Health Statistics for each year 1917 through 1980. To summarize the fertility experience for a single year, total fertility rates were used. The total fertility rate is a simple sum of the age-specific birth rates applicable during the year. Thus the total fertility rate can be interpreted as the number of children that would be born to a woman if she were to survive her childbearing years and were to experience those age-specific birth rates throughout her childbearing years.

As a first step in projecting fertility, it is instructive to examine the recent history of fertility in the United States. During the period 1917 to 1925, the total fertility rate was more than three children per woman. During the period 1924 to 1933 the total fertility rate declined from 3.1 to 2.2 children per woman, and then remained level at 2.1 to 2.2 children per woman through 1940. During the next 20 years, the total fertility rate increased unsteadily to more than 3.6 children per woman. Throughout the 1960's and early 1970's, the total fertility rate declined steadily to a low point of 1.7 in 1976. Since then, the total fertility rate has been about 1.8 children per woman.

We believe that the total fertility rate will eventually increase above the present low level, but that it will not return to the high levels observed during the late 1940's, the 1950's, and the early 1960's. We believe that the total fertility rate will ultimately exceed the present low level because such a total fertility rate has never been experienced in the United States over a long period of time and because such a level is below that needed to maintain the size of the population in the absence of increased net immigration. A rate of 2.1 would result in a nearly constant population if net immigration were equal to zero and if mortality rates were constant at levels close to current U.S. experience. We believe that the total

fertility rate will not return to the high levels observed in the past because of the increased availability and use of birth control methods, changes in the roles of women in our society, the increased prevalence of divorce, the increased postponement of marriage among young women, and the shift in the perception of the status of children within their families from economic assets to economic liabilities. Recent birth expectation surveys, such as that published by the Bureau of the Census in the Current Population Reports, Series P-20, No. 395, are consistent with a long-range assumption for the total fertility rate in the neighborhood of 2.0-2.1 children per woman. Thus, an ultimate total fertility rate of 2.0 children per woman was selected as the intermediate (Alternative II) assumption for the 1985 Report of the Board of Trustees.

To help in selecting ultimate rates for Alternatives I and III, an examination of the recent total fertility rates in other nations is useful. A comparison of the total fertility rates in 1976 in the U.S., Canada, and fifteen countries in Western Europe revealed a range of 3.5 in Ireland to 1.5 in West Germany. The U.S. ranked eighth with 1.74. Four of these countries had a total fertility rate over 2.3 and two countries had a total fertility rate under 1.6. For reasons already cited, we do not believe that the total fertility rate for the U.S. will return to such a level as high as 3.5, and have selected 2.3 as the optimistic (Alternative I) assumption. It is plausible that the total fertility rate could be as low as 1.6 children per woman over a long period of time. Thus, we have selected 1.6 as the pessimistic (Alternative III) assumption. The ultimate values selected for the 1985 Trustees Report compare closely with those used by the Bureau of the Census in its latest series of population projections, published in Current Population Reports, Series P-25, No. 952. The Bureau of the Census used a range of 1.6 to 2.3, with an intermediate assumption of 1.9. The ultimate total fertility rate for each alternative was assumed to be first reached in calendar year 2009.

Total fertility rates for 1981 through 1984 were estimated from provisional data published by the National Center for Health Statistics in Monthly Vital Statistics Reports, Volumes 30 through 33. Between 1984 and 2009, the age-specific birth rates were projected separately for each cohort of women such that the completed cohort fertility rate would gradually approach the assumed ultimate total fertility rate. Table 4 gives past and assumed total fertility rates by alternative. Chart 1 gives past and assumed total fertility rates for 1920-2080. Tables 3a, 3b, and 3c give the assumed age-specific birth rates by alternative for selected calendar years.

## 2. Mortality

Death rates are defined as the number of deaths during the year divided by the mid-year population. These rates were calculated by sex on an age-specific basis for each year 1900 through 1981. To summarize the mortality experience of a single year and to control for changes in the age distribution of the population from year to year, age-adjusted death rates (as shown in Table 7a) were calculated as a weighted average of the age-specific death rates, where the weights were the number of people in the

corresponding age groups of the 1970 U.S. census population. Thus, if the age-adjusted death rate for a particular year and sex is multiplied by the 1970 U.S. census population, the result gives the number of deaths that would occur in the 1970 U.S. census population in a year if the age-specific death rates for that particular year and sex were to be experienced. The age-adjusted death rate is, therefore, equivalent to the crude death rate that would be experienced in the 1970 U.S. census population.

An examination of the age-adjusted death rates since 1900 reveals four distinct periods of mortality reduction. During the period 1900 to 1936, annual mortality reduction averaged about 0.9 percent for males and 1.0 percent for females. Following this was a period of rapid reduction, 1936-1954, in which mortality decreased an average of 1.7 percent per year for males and 2.6 percent for females. The period 1954 to 1968 saw an actual increase for males of 0.1 percent per year and a much slower reduction of 0.8 percent per year for females. From 1968 through 1981 rapid reduction in mortality resumed averaging 1.8 percent for males and 2.2 percent for females, annually. Provisional statistics for 1982 show greater mortality reduction from the 1981 level than the average experienced during 1968 through 1981 while partial statistics for 1983 show only a slight reduction from the 1982 level.

Age-sex-adjusted death rates are often calculated when one is interested in summarizing death rates for both sexes combined. Age-sex-adjusted death rates (as shown in Table 7b) were calculated as a weighted average of the age-sex-specific death rates where each weight was the number of people in the corresponding age and sex group of the 1970 U.S. census population.

Past reduction in mortality has varied greatly by cause of death. Because it is expected that future reduction in mortality rates will also vary greatly by cause of death, death rates for the years 1968 through 1981 were calculated and analyzed by age group and sex for ten groups of causes of death. These groups are as follows:

- I. Diseases of the Heart (Ninth Revision of the International List of Diseases and Causes of Death code numbers 390-398, 402, 404-429)
- II. Malignant Neoplasms (140-208)
- III. Vascular Diseases (400-401, 403, 430-459, 582-583, 587)
- IV. Accidents, Suicide, and Homicide (E800-E989)
- V. Diseases of the Respiratory System (460-519)
- VI. Congenital Malformations and Diseases of Early Infancy (740-779)
- VII. Diseases of the Digestive System (520-570, 572-579)
- VIII. Diabetes Mellitus (250)
- IX. Cirrhosis of the Liver (571)
- X. All Other Causes

For the years 1968-1981, death rates for ages under 65 by age group, sex, and cause of death were calculated using the numbers of deaths as tabulated in Vital Statistics of the United States and using the latest census estimates of the resident population as published in the P-25 Series of Current Population Reports. For the years 1968 through 1978, an adjustment was made to the distribution of the numbers of deaths among the ten causes. This adjustment was needed in order to reflect the revision in the cause of death coding that occurred in 1979, thereby making the data for the years 1968 through 1978 more comparable with the coding used for the years 1979 and later. The adjustments were based on comparability ratios published by the National Center for Health Statistics in Monthly Vital Statistics Report, Volume 28, Number 11. For the ages 65 and over, records of the Medicare program were used to determine rates by age and sex. The numbers of deaths by cause in Vital Statistics of the United States were used to distribute the age-sex specific death rates for ages over 65 into age-sex-cause specific death rates. A detailed analysis of Medicare mortality statistics and a comparison to the statistics provided by the National Center for Health Statistics is contained in "Recent Trends in the Mortality of the Aged" by John C. Wilkin in the Transactions of the Society of Actuaries, Volume XXXIII.

Average annual reductions in mortality were determined for the period 1968-1981 by age group, sex, and cause of death. The results, shown in Table 5, were calculated as the complement of the exponential of the slope of the least-squares line through the logarithms of the death rates. The sharpest reductions were in the category of Congenital Malformations and Diseases of Early Infancy and the category of Vascular Disease, averaging 4 1/2 to 5 1/4 percent per year. Diabetes Mellitus averaged about 3 1/4 percent reduction per year. Averaging 2 to 2 1/2 percent average reduction per year were Heart Diseases, Digestive Disease, and Violence. At about 1 1/2 percent average reduction per year were Respiratory Disease and Cirrhosis of the Liver, while the residual group of other Causes averaged about 1/4 percent reduction per year. Malignant Neoplasms was the only cause from the above group for which mortality increased during this period, increasing at about 1/2 percent per year.

Future improvements in mortality will depend upon such factors as the development and application of new diagnostic, surgical, and life-sustaining techniques, the presence of environmental pollutants, improvements in exercise and nutrition, the incidence of violence, the isolation and treatment of causes of disease, the emergence of new forms of disease, improvements in prenatal care, the prevalence of cigarette smoking, the misuse of drugs (including alcohol), the extent to which people assume responsibility for their own health, and changes in our conception of the value of life. After considering how these and other factors might affect

mortality, we postulated three alternative sets of ultimate annual percentage reductions in death rates by sex and cause of death for the years 2009 and later. These ultimate annual percentage reductions are as follows:

Assumed Ultimate Annual Percentage Reductions in  
Death Rates by Alternative, Sex, and Causes

| Alternative<br>and Sex | I   | II  | III | IV  | V   | VI  | VII | VIII | IX  | X   |
|------------------------|-----|-----|-----|-----|-----|-----|-----|------|-----|-----|
| Alternative I          |     |     |     |     |     |     |     |      |     |     |
| Male                   | 0.5 | 0.0 | 0.7 | 0.1 | 0.1 | 0.7 | 0.3 | 0.2  | 0.1 | 0.0 |
| Female                 | 0.5 | 0.0 | 0.7 | 0.1 | 0.1 | 0.7 | 0.3 | 0.2  | 0.1 | 0.0 |
| Alternative II         |     |     |     |     |     |     |     |      |     |     |
| Male                   | 0.7 | 0.2 | 1.0 | 0.2 | 0.1 | 1.0 | 0.6 | 0.4  | 0.2 | 0.2 |
| Female                 | 0.7 | 0.3 | 1.0 | 0.2 | 0.2 | 1.0 | 0.6 | 0.5  | 0.2 | 0.2 |
| Alternative III        |     |     |     |     |     |     |     |      |     |     |
| Male                   | 1.0 | 1.2 | 1.3 | 0.3 | 0.4 | 1.5 | 1.0 | 0.8  | 0.4 | 0.4 |
| Female                 | 1.0 | 1.5 | 1.5 | 0.4 | 0.5 | 1.5 | 1.0 | 1.0  | 0.4 | 0.4 |

Future reductions for those under 65 are projected to be relatively small compared with past reductions because very little additional improvement in infectious diseases (such as poliomyelitis and influenza) is possible and because only a small reduction in mortality from violent causes (accidents, suicide, and homicide) is expected. Reductions for the aged are expected to continue at a relatively rapid pace, as further advances are made against degenerative diseases (such as heart and vascular disease). The gap between male and female mortality is expected to continue widening, but at a decreased rate as women become increasingly subject to many of the same environmental hazards and social pressures as men. After adjustment for changes in the age and sex distribution of the population, Alternative II mortality is projected to decrease at an average rate of about 0.6 percent per year during the period 1983-2060. This is about half the average annual reduction observed during 1900-1983. During the period 1983-2060, Alternative I mortality is projected to reduce by about one-fourth the average rate observed during 1900-1983, while for Alternative III mortality, the average annual reductions during these two periods are almost the same.

Death rates by age group, sex, and cause of death for 1982 were estimated from provisional data published by the National Center for Health Statistics in Monthly Vital Statistics Reports, Volume 31. Death rates for 1983 were assumed to change from 1982 by amounts estimated from data published in Monthly Vital Statistics Reports, Volume 32. Death rates were projected by age group, sex, and cause of death from their estimated 1983 levels by applying annual percentage reductions. The annual reductions applied to obtain the 1984 levels were 50 percent, 100 percent, and 150 percent of the

average annual reductions during 1968-1981 <sup>1/</sup> for Alternatives I, II, and III, respectively. The annual reductions assumed to apply during 1984-2008 were calculated by a logarithmic formula designed to gradually transform the reductions applied to obtain the 1984 levels into the postulated ultimate annual reductions. The ultimate reductions were assumed to apply during 2009-2080. Tables 6a, 6b, and 6c give the resulting death rates by age group, sex, and alternative for selected years.

Tables 8a and 8b give the resulting life expectancies for males and females at birth and at age 65, respectively, for historical years and by alternative for selected future years. Life expectancy for any year is the number of years of life remaining for a person who is assumed to experience the death rates by age observed in or assumed for the selected year. Thus, the life expectancies present in Table 8a are summary statistics of the overall mortality for the applicable calendar year. Similarly, the life expectancies in Table 8b summarize the mortality at ages 65 and older for the applicable calendar year.

Chart 2 is a graph of the past and projected life expectancies of males and females at birth from 1900 to 2080 by alternative. Rapid gains in expectancy at birth occurred from 1900 through the mid-1950's for both males and females. From the mid-1950's through the mid-1960's, male life expectancy at birth remained level, while female life expectancy at birth increased moderately. During the 1970's rapid gains resulted for both males and females. Under all three alternatives, the life expectancy at birth is projected to increase. For males, the life expectancy at birth increases from 71.1 years in 1983 to 74.7 years, 77.9 years, and 84.0 years in 2080 under Alternatives I, II, and III, respectively. This represents an increase ranging from 3.6 years to 12.9 years. For females the increase ranges from 3.7 years to 13.7 years over the 78.3 years in 1983, to 82.0 years, 85.7 years, and 92.0 years in 2080 under Alternative I, II, and III, respectively. The difference between male and female life expectancies is projected to increase from 7.2 years in 1983 to 7.3 in 2080 under Alternative I, to 7.8 under Alternative II, and to 8.0 under Alternative III.

Life expectancy at age 65 for males increased from 11.35 years in 1900 to 14.25 years in 1981, while life expectancy at age 65 for females increased from 12.01 years to 18.59 years. The life expectancy for males at age 65 is projected to increase from 14.5 years in 1983 to 16.5 years, 18.6 years, and 23.3 years in 2080 under Alternatives I, II, and III, respectively. This represents an increase ranging from 2.0 years to 8.8 years. For females the increase ranges from 2.8 years to 10.5 years. The female age 65 life expectancy is projected to increase from 18.8 years in 1983 to 21.6 years, 24.4 years, and 29.3 years under Alternatives I, II, III, respectively. It is interesting to note that the difference in life expectancy between

<sup>1/</sup> The average annual reductions for the "All Other" category for age 0 were calculated using the period 1974-1981, rather than 1968-1981. This was done because of a distinct shift in the earlier trend that occurred in 1974, making the earlier data inappropriate for this category.

females and males at age 65 has increased from .66 years to 4.34 years between 1900 and 1981. The sex gap in life expectancy at age 65 is projected to increase to 5.1, 5.8, and 6.0 years by 2080 under Alternatives I, II, and III, respectively.

Although a complete projection of age-sex-specific death rates was not done for each marital status, historical data indicated that the differential in mortality by marital status is important. Thus, future relative differences in death rates by marital status were projected based on recent experience during calendar years 1980 and 1981. Death rates for this period are shown in Table 9. These rates were calculated using deaths as tabulated from the 1980 and 1981 Mortality Cause-of-Death Summary Public Use Data Tapes available from the National Center for Health Statistics and population distributions as published in Current Population Reports, Series P-20 and P-25, by the Bureau of the Census.

### 3. Net Immigration

Immigration was once a very important element in the growth of the United States population. During calendar years 1904 through 1913 for example, immigration averaged nearly one million per year, which represented quite sizeable percentage increases in the United States population. Immigration decreased greatly during World War I and following the adoption of quotas based on national origin in 1921. The economic depression in the 1930's caused an additional but temporary decrease, which resulted in more emigration than immigration. Annual immigration increased after World War II to around 300,000 persons per year and stayed at that level through the 1950's and into the 1960's. With the Immigration Act of 1965 and other related changes, annual immigration increased to about 400,000. During the last four years of available data (1978-1981), however, immigration has averaged approximately 550,000 per year. Although statistics on emigration are sparse and largely estimated (see, "Foreign-Born Emigration From the United States: 1960 to 1970" by Warren and Peck in Demography, February 1980), they suggest that annual emigration has been over 100,000.

In deciding upon the annual net immigration (excess of immigration over emigration) to be assumed for future years, the question of making some provision for persons entering the United States illegally arises. Illegal aliens are included in our starting population, consistent with the official policy of the Bureau of Census to enumerate or to include in the estimated undercount all persons residing in the U.S., whether legally or illegally. Illegal immigration seems to explain in part the "error of closure" that was evidenced in the 1980 census. The 1980 census enumerated about 5.5 million more persons than were previously estimated for April 1, 1980. We have decided, however, not to include in our projections aliens who may enter the United States illegally after July 1, 1983, largely because no reliable estimate of their exact number exists. Part of the problem in analyzing net illegal immigration is that many illegal aliens tend to stay in the United States temporarily rather than permanently, as they frequently return to families in their native countries.

For the 1985 Report of the Board of Trustees, net immigration is assumed to be 700,000, 500,000, and 300,000 persons per year for Alternatives I, II and III, respectively. The assumptions selected for Alternatives I and II assume refugees will be admitted periodically, over and above the annual quotas provided in present law. The age-sex distribution of the assumed net annual immigration was based on data supplied by the Immigration and Naturalization Service on immigration during the 1970's. An error in the age-sex distribution was present in the 1983 and 1984 population projections prepared by our office. This error was corrected in the 1985 projections and the resulting age-sex distributions for the three Alternatives are shown in Table 10.

#### 4. Marriages

Because marriage is the combination of a male and a female into a couple, marriage rates can be computed as a ratio of the number of marriages to (1) the number of nonmarried males (not taking into account the number of nonmarried females), (2) the number of nonmarried females (not taking into account the number of nonmarried males), or (3) a theoretical number of nonmarried couples that takes into account both the number of nonmarried males and nonmarried females. The marriage rates referred to in this study are computed using the third concept of a theoretical number of nonmarried couples as the denominator. The rates were computed as the number of marriages for given ages of husband and wife divided by the square root of the product of the mid-year nonmarried males and nonmarried females of the given ages.

In order to calculate these rates, data on new marriages in the Marriage Registration Area (which in 1978 consisted of 41 States and D.C. and accounted for about 80 percent of all marriages in the U.S.) were obtained from the National Center for Health Statistics for calendar years 1957 through 1981 by age of husband crossed with age of wife. Estimates of the nonmarried population in the Marriage Registration Area were obtained from the National Center for Health Statistics and from the Bureau of the Census by age group and sex.

The number of marriages depends upon the age distribution of both the nonmarried male population and the nonmarried female population. Thus, an acceptable summary statistic could be calculated by age-adjustment to a set of standard nonmarried populations. When only one population is involved (as in calculating death rates), equal results are obtained by viewing the age-adjusting concept as the weighted average of the age-specific rates or as the crude rate that would occur in the standard population. When two populations are involved (as in calculating marriage rates), these two concepts do not produce the same results. In either case, the number of marriages that would occur in the standard population is first calculated by applying the age\*of\*husband-age\*of\*wife-specific marriage rates to the square root of the product of the corresponding standard age-specific populations. The weighted average of the rates is obtained by dividing the resulting total number of marriages by the sum of all of the factors to which the marriage rates were applied, while the crude rate is obtained by dividing the total number of marriages by the square root of the product of

the total male nonmarried population and the total female nonmarried population. In this study we have calculated rates for the years 1957 through 1981 under the latter concept, i.e., the crude rate that would be experienced in the standard population, which we express per hundred thousand nonmarried of each sex. Table 13 displays the age-adjusted marriage rates for each year during the period 1957 through 1981. The total rates ranged from a high in 1968 of 9,822 per hundred thousand nonmarried persons of each sex to a low in 1981 of 5,867. The total age-adjusted rate remained relatively constant during the late 1950's and throughout the 1960's. A major decrease in the total age-adjusted rate was experienced during the 1970's with the largest part of the decrease attributable to the age groups 14-19 and 20-24.

Because we are uncertain whether marriage rates will increase or decrease, we assumed that future rates of marriage would remain at the same level as observed during the 12 months ending with June 1984. The age\*of\*husband-age\*of\*wife-specific rates observed in 1979 and 1981 were averaged and adjusted to this level. These rates for five-year age groups are shown in Table 11. Of course, use of constant age-specific rates does not imply that the crude rate of marriage in the projected population remains constant.

Although a complete projection of age\*of\*husband-age\*of\*wife-specific marriage rates was not done for each previous marital status, experience data indicated that differential in marriage rates by previous marital status is important. Future relative differences in marriage rates by previous marital status were assumed to be the same as the average of those experienced during 1979 and 1981. These rates were obtained from unpublished data supplied by the National Center for Health Statistics, which with slight modifications are given in Table 12.

## 5. Divorce

The unavailability of data for an acceptable representative statistic for divorces precluded us from effectively studying past trends in divorce. Hence we assumed that future age\*of\*husband-age\*of\*wife-specific rates of divorce would remain at about the same level as recently observed. Of course, this does not imply that the crude rate of divorce in the projected population remains constant.

Data on divorces (including annulments) in the Divorce Registration Area during calendar years 1979 and 1981 by age group of husband crossed with age group of wife were obtained from the National Center for Health Statistics. For each calendar year 1979 and 1981, the divorces occurring in the Divorce Registration Area (which in 1978 consisted of 29 States and accounted for about 60 percent of all divorces in the U.S.) were inflated to represent the Social Security Area, based on the total number of divorces during the corresponding calendar year in the 50 States, District of Columbia, Puerto Rico, and the Virgin Islands. Divorce rates for each age group of husband crossed with each age group of wife were then calculated as the ratio of the number of divorces in the Social Security Area for couples within the given ages of husband and wife to the number of existing marriages in the Social Security Area within the given ages of husband and wife. The resulting rates for 1979 and 1981 were averaged and then adjusted to the level observed during the 12 months ending with June 1984. The final rates are shown in Table 14.

## D. METHODS

### 1. Probabilities of Survival

Earlier in this study, death rates (generally referred to as central death rates) have been calculated as the number of deaths occurring in a given year divided by the mid-year population in that year. This concept is a useful one in the context of analyzing historical trends, but is not so readily applicable to the actual projection of population. What is more suitable is the concept of probability of death (or of survival). This concept involves dividing the number of deaths occurring to a group in a given year by the number of persons in that group at the beginning of the year (rather than the population at the middle of the year). As one would expect, these two concepts are closely related, although the mathematics of their relationship is not trivial.

Future probabilities of survival by age last birthday were calculated for each sex and each single year of age from the projected central death rates by sex and age group. The probability of death at age 0 ( $q_0$ ) was calculated from the population central death rate for age 0 and the relationship between the probability of death and the central death rate that existed in 1981. For each single year of age 1 through 4, the probability of death was calculated from the population central death rate for age 1 through 4 ( ${}_4m_1$ ) and the relationships that existed in 1981. Probabilities of death at ages 5 and older were calculated by an iterative method. As a first approximation, the probability of death for each five-year age group from 5-9 to 90-94 was calculated from the corresponding central death rate using the same method Greville used in constructing the 1959-61 United States Life Tables. As part of the iterative process, the probability of death for each single age in each five-year age group was determined by interpolating the logarithms of the complements of the surrounding five-year probabilities of death with Beer's minimized fifth-difference formula. The probability of death for each age 95 and over was calculated to produce a rapid decline in the ratio of succeeding probabilities of death to a minimum ratio of 1.05 for females and 1.04 for males. These ratios were chosen based on the analysis by Francisco R. Bayo and Joseph F. Faber contained in the paper "Mortality Experience Around Age 100," in the Transactions of the Society of Actuaries, Volume XXXV. A life table for each sex was then constructed using these probabilities of death. On subsequent iterations, the life table probability of death for each age 5 through 94 was adjusted so that the central death rates for the five-year age groups obtained by weighting the single age life table central death rates by the population would equal the corresponding population five-year age group central death rates. This adjustment corrects for the fact that the distribution within each quinquennial age group in the life table population generally differs from that in the actual population. For more detail on the method used to produce the life tables for these population projections see Actuarial Study No. 89, "Life Tables For The United States: 1900-2050" by Joseph F. Faber and Alice H. Wade.

For those born during the year, the probability of survival to the end of the year was calculated as the ratio of the stationary population between ages 0 and 1 ( $L_0$ ) to the number of new births ( $i_0$ ). For each age 0 to 99, the probability of survival to the next age was calculated as the ratio of the stationary population at the succeeding age ( $L_{x+1}$ ) to the stationary population at the age ( $L_x$ ). For the group aged 100 and over, the probability of survival for one year was calculated as the ratio of the stationary population at ages 101 and over ( $T_{101}$ ) to the stationary population at ages 100 and over ( $T_{100}$ ).

## 2. Probabilities of Marriage and Divorce

Probabilities of marriage were calculated for each age of husband crossed with each age of wife from the average of the marriage rates for calendar years 1979 and 1981 so as to reproduce a provisional estimate of the number of marriages in the Social Security Area from July 1, 1983 to July 1, 1984. The calculation was necessarily iterative, because the probability of marriage to a partner at a given age is dependent upon the probabilities of marriage to partners of other ages. Probabilities of divorce were calculated for each age of husband crossed with each age of wife from the average of the divorce rates for the calendar years 1979 and 1981 so as to reproduce a provisional estimate of the number of divorces in the Social Security Area from July 1, 1983 to July 1, 1984. The provisional estimates of marriages and divorces were developed from data published by the National Center for Health Statistics in Monthly Vital Statistics Reports, Volume 33.

## 3. Deaths

The number of deaths occurring at each age and sex was calculated as the difference between the number of people alive at the beginning of the year and the product of the number of people alive at the beginning of the year and the probability of survival. Deaths to new born babies were computed using a similar formula. However, deaths to immigrants newly arriving in the year were disregarded. The numbers of deaths were then distributed by marital status in the same proportions as would have been produced by applying the marital-status specific probabilities of survival to the population by marital status at the beginning of the year. Projected numbers of deaths are given in Table 15 by alternative.

## 4. Marriages

The number of marriages occurring at each age of husband crossed with each age of wife was calculated iteratively as the product of the probability of marriage and the square root of the product of the male population exposed to marriage and the female population exposed to marriage. (The male population exposed to marriage was approximated as the nonmarried male population of the given age at the beginning of the year less one-half of all marriages to females of ages other than the given age of the female. The female population exposed to marriage was approximated similarly). The numbers of marriages were then distributed by previous marital status in the

same proportions as would have been produced by applying the previous-marital-status-specific marriage rates to the population by marital status at the beginning of the year. Projected numbers of marriages are given in Table 15 by alternative.

#### 5. Widowings

The number of marriages dissolved by death at each age of husband crossed with each age of wife was calculated by applying joint-life probabilities of death to the existing marriages by age of husband crossed with age of wife at the beginning of the year. (The joint-life probabilities were developed to be consistent with the projected death rates and the assumed mortality differential by marital status, and assumed independence of the partners). The number of widowings for a particular age and sex was calculated as the difference between the marriages of individuals of that particular age and sex dissolved by death of either partner and the number of deaths to married persons of that age and sex. Projected numbers of widowings are given in Table 15 by alternative.

#### 6. Divorces

The number of marriages dissolved by divorce at each age of husband crossed with each age of wife was calculated by applying probabilities of divorce to the existing marriages by age of husband crossed with age of wife at the beginning of the year. Projected numbers of divorces are given in Table 15 by alternative.

#### 7. Net Immigration

The assumed net immigration for each age and sex was distributed among the single (never married), widowed, and divorced populations in the same proportions as existed in the nonmarried population at the beginning of the year. None of the immigrants during the year were assigned to the married population because of the relatively small numbers involved and because of the lack of information of age of spouse.

#### 8. End-of-Year Population

The single (never married) population at the end of the year for each age and sex was calculated from the single population at the beginning of the year by subtracting the deaths and marriages during the year, and adding the net immigration of single persons. The married population at the end of the year was calculated from that at the beginning of the year by subtracting the deaths and divorces, and adding the marriages. The widowed population at the end of the year was calculated by subtracting the deaths and marriages, and adding the widowings and net immigration. The divorced population at the end of the year was calculated by subtracting the deaths and marriages, and adding the divorces and net immigration.

The existing marriages at the end of the year by age of husband crossed with age of wife were calculated from the existing marriages at the beginning of the year by subtracting the marriages dissolved by death and those dissolved by divorce and adding the new marriages during the year. The methods used assured consistency between the married population by age and sex at the end of the year and the existing marriages at the end of the year.

#### 9. Births

Birth rates covering July 1 to June 30 were approximated from those covering January 1 to December 31 by linear interpolation. These rates were then applied to the average of the beginning-of-year and end-of-year female populations to calculate births during the year. Projected numbers of births are given in Table 15 by alternative.

## E. RESULTS

### 1. Total Population

Tables 18a-18h, 19a-19h, and 20a-20h give projections of the Social Security Area population by age group, sex, marital status, and alternative for selected years. Tables 17a-17e give similar figures for historical years. The past and projected total population is shown graphically in Chart 3. Under Alternative I (with greater-than-replacement fertility), the total population increases rapidly from 243 million in 1983 to 469 million in 2080. Under Alternative II, the total population increases gradually to 342 million in 2080 as a 2.0 total fertility rate plus 500,000 annual net immigrants are slightly more than enough to replenish the population. Under Alternative III, the total population increases to 283 million in 2022 and then decreases to 225 million in 2080. The decline in population size after 2022 is due to the compounding effect of below-replacement fertility which is only partially offset by the positive net immigration.

The proportion of the population which is single in 2080 is projected to be 43 percent (the same as it was in 1983) under Alternative I, to decrease to 38 percent under Alternative II, and to decrease to 30 percent under Alternative III, reflecting differences in the age distribution of the population among the three alternatives. The proportion married is projected to change from 46 percent in 1983 to 44, 47, and 52 percent in 2080, under Alternatives I, II, and III, respectively. The proportion widowed in 2080 is projected to change from 6 percent in 1983 to 7 and 9 percent, under Alternatives II and III, respectively, and to remain at 6 percent under Alternative I. The current high incidence of divorce, which is assumed to continue in the future, causes the proportion divorced to increase greatly from 5 percent in 1983 to 7 percent under Alternative I, to 8 percent under Alternative II, and to 9 percent under Alternative III in 2080.

### 2. Aged Population

A rough estimate of the growth in the number of persons receiving Social Security retirement benefits can be obtained from examining the age 65-and-over population given in Tables 16a-16c. The projected population at ages 65 and older is also shown graphically in Chart 4. The growth in the number of people age 65 and older slows down around the year 2000 due to the low fertility experience during the 1930's. This slowing down is not as great under Alternatives II and III because assumed mortality reductions are greater than under Alternative I. The high fertility of the 1950's and 1960's results in sharp steady growth in the 65-and-over population throughout the period 2010-2030 under all of the alternatives. By the year 2080, the 65-and-over population as a percentage of total population increases significantly from 11 percent in 1983 to 17 percent under Alternative I, 22 percent under Alternative II, and 35 percent under Alternative III.

### 3. Demographic Indicators

The projected population is summarized by broad age group and alternative for selected years in Table 16. The broad age groups are under 20, 20 to 64, and 65 and over. Tables 16a-16c also summarizes the projected total population by marital status.

The aged dependency ratio given in Tables 16a-16c is the ratio of the number of persons aged 65 and over to the number of persons aged 20 to 64. This ratio is closely related to the ratio of retirees to workers and, thus, provides an index of possible future demographic pressures which may be faced by Social Security. Under Alternative I, the aged dependency ratio is projected to increase from .196 in 1983 to .344 in the year 2031 and then to decrease to an ultimate level of about .305. Under Alternative III, the aged dependency ratio is projected to increase to .410 in 2036 and then to stay around that level. Under Alternative III, the aged dependency ratio is projected to increase throughout the entire projection period to .711 in the year 2080. A sharp increase in the aged dependency ratio shortly after the turn of the century appears certain as the baby-boom generation attains age 65 while the baby-bust generation attains age 20. The magnitude of the increase, however, will depend upon future mortality reductions among the aged and future fertility rates. Even under optimistic assumptions, however, the aged dependency ratio will increase 75 percent by the year 2030.

Since not everyone retires at age 65 and since the minimum age at which unreduced benefits are payable is scheduled to increase, it is interesting to observe the aged dependency ratio using cutoff ages other than 65. Table 21 displays these ratios at age 62 when retired worker benefits are first available, at age 67 which will be the normal retirement age (i.e., the minimum age at which unreduced retirement benefits are payable) after 2026, and age 70 after which delayed retirement credits can no longer be earned. In Table 22 the ages necessary to maintain an aged dependency ratio of .20, .25, and .30 are given. In order to maintain an aged dependency ratio of .20 (the approximate age 65 dependency ratio in 1983) the aged dependency ratio in 2080 must be calculated at ages 70, 75, and 83 under Alternatives I, II, and III, respectively. Under all three alternatives, the age necessary to maintain a selected aged dependency ratio increases rapidly from 2010 to 2040.

The total dependency ratio given in Tables 16a-16c is the ratio of the number of persons who are under age 20 or over age 64 to the number of persons aged 20 to 64. This ratio views the possible future financial burdens to be borne by workers from a somewhat broader perspective. Under all three alternatives, the total dependency ratio is projected to decrease from .714 in 1983 until shortly after the turn of the century, reflecting the small number of children resulting from the low fertility rates experienced since 1970 and projected to be experienced in the near future, and the slow growth in the aged population resulting from the low fertility rates experienced during the 1930's. Starting around 2010, the total dependency ratios begin to rise, largely reflecting the same effects that

influence the aged dependency ratios. Projected values of the total dependency ratio in 2080 range from .835 under Alternative I to 1.046 under Alternative III or roughly from 17 to 46 percent higher than the 1983 value.

The disunity ratio given in Tables 16a-16c is the ratio of the number of divorced persons to the sum of the numbers of married and widowed persons. Assuming a continuation of the current high incidence of divorce, this ratio will increase by approximately 45 percent by the turn of the century. Chart 6 compares the distribution of the population by marital status in 1983 with the projected distribution in 2080.

Table 1. July 1, 1983 Population in the Social Security Area, by Age, Sex, and Marital State (in thousands)

| Sex and Marital State |        |        |        |         |         |          |        |        |         |         |          |
|-----------------------|--------|--------|--------|---------|---------|----------|--------|--------|---------|---------|----------|

Note: The total fertility rate is the average number of children that would be born to a woman if she were to survive the childbearing period and were to experience the age-specific central birth rates for the tabulated year throughout that period.

**Table 5. Average Annual Percentage Reductions in Central Death Rates during 1968-81, by Age, Sex, and Cause of Death**

| Sex    | Age   | Total | Cause of Death |        |                  |          |                     |         |                   |                   |                 |        |
|--------|-------|-------|----------------|--------|------------------|----------|---------------------|---------|-------------------|-------------------|-----------------|--------|
|        |       |       | Heart Disease  | Cancer | Vascular Disease | Violence | Respiratory Disease | Infancy | Digestive Disease | Diabetes Mellitus | Liver Cirrhosis | Other  |

Note: The first step in calculating the total age-adjusted central marriage rate for a particular year is to determine an expected number of marriages by applying the age-of-husband-age-of-wife-specific central marriage rates for that year to the square root of the product of the corresponding age groupings of unmarried males and unmarried females in the 1980 census population. The total age-adjusted central marriage rate is then obtained by dividing the expected number of marriages by the square root of the product of the number of unmarried males (aged 15 and over) and unmarried females (aged 15 and over) in the 1980 census population. The age-adjusted central marriage rate for a particular age-sex grouping is calculated in a similar manner. Instead of the standard population being the total 1980 census population, it reduces to the particular age-sex grouping and all members of the opposite sex.

Table 14. Assumed Central Divorce Rates, by Ages of Husband and Wife  
(per hundred thousand)

| Age of Husband | Age of Wife |        |        |        |        |        |        |        |
|----------------|-------------|--------|--------|--------|--------|--------|--------|--------|

Note: The aged dependency ratio is the ratio of the number of persons aged 65 and older to the number of persons aged 20 to 64. The total dependency ratio is the same as the aged dependency ratio except the number of persons under age 20 are also included in the numerator of the ratio. The disunity ratio is the ratio of the number of divorced persons to the number of married and widowed persons.

Note: The aged dependency ratio is the ratio of the number of persons aged 65 and older to the number of persons aged 20 to 64. The total dependency ratio is the same as the aged dependency ratio except the number of persons under age 20 are also included in the numerator of the ratio. The disunity ratio is the ratio of the number of divorced persons to the number of married and widowed persons.

Table 16c. Alternative III Population in the Social Security Area as of July 1 and Selected Ratios, by Year

| Year | Marital State |         |         |          | Total  | Population (in thousands) |        |        | Dependency Ratio |      |       |      |
|------|---------------|---------|---------|----------|--------|---------------------------|--------|--------|------------------|------|-------|------|
|      | Single        | Married | Widowed | Divorced |        | Age                       | 0-19   | 20-64  | 65+              | Aged | Total |      |

Note: The aged dependency ratio is the ratio of the number of persons aged 65 and older to the number of persons aged 20 to 64. The total dependency ratio is the same as the aged dependency ratio except the number of persons under age 20 are also included in the numerator of the ratio. The disunity ratio is the ratio of the number of divorced persons to the number of married and widowed persons.

Table 17a. July 1, 1940 Population in the Social Security Area, by Age, Sex, and Marital State (in thousands)

| Age        | Total  | Male  |        |         |         |          |          | Female |        |         |         |          |          |
|------------|--------|-------|--------|---------|---------|----------|----------|--------|--------|---------|---------|----------|----------|

Note: The aged dependency ratio calculated at a selected age is the ratio of the number of people in the population as of July 1 who are as old or older than the selected age to the number of people in the population as of July 1 who are between age 19 and the selected age.

Chart 1.

Total Fertility Rate (in children per woman): 1920-2080  
Actual and as Projected under Alternatives I, II, and III

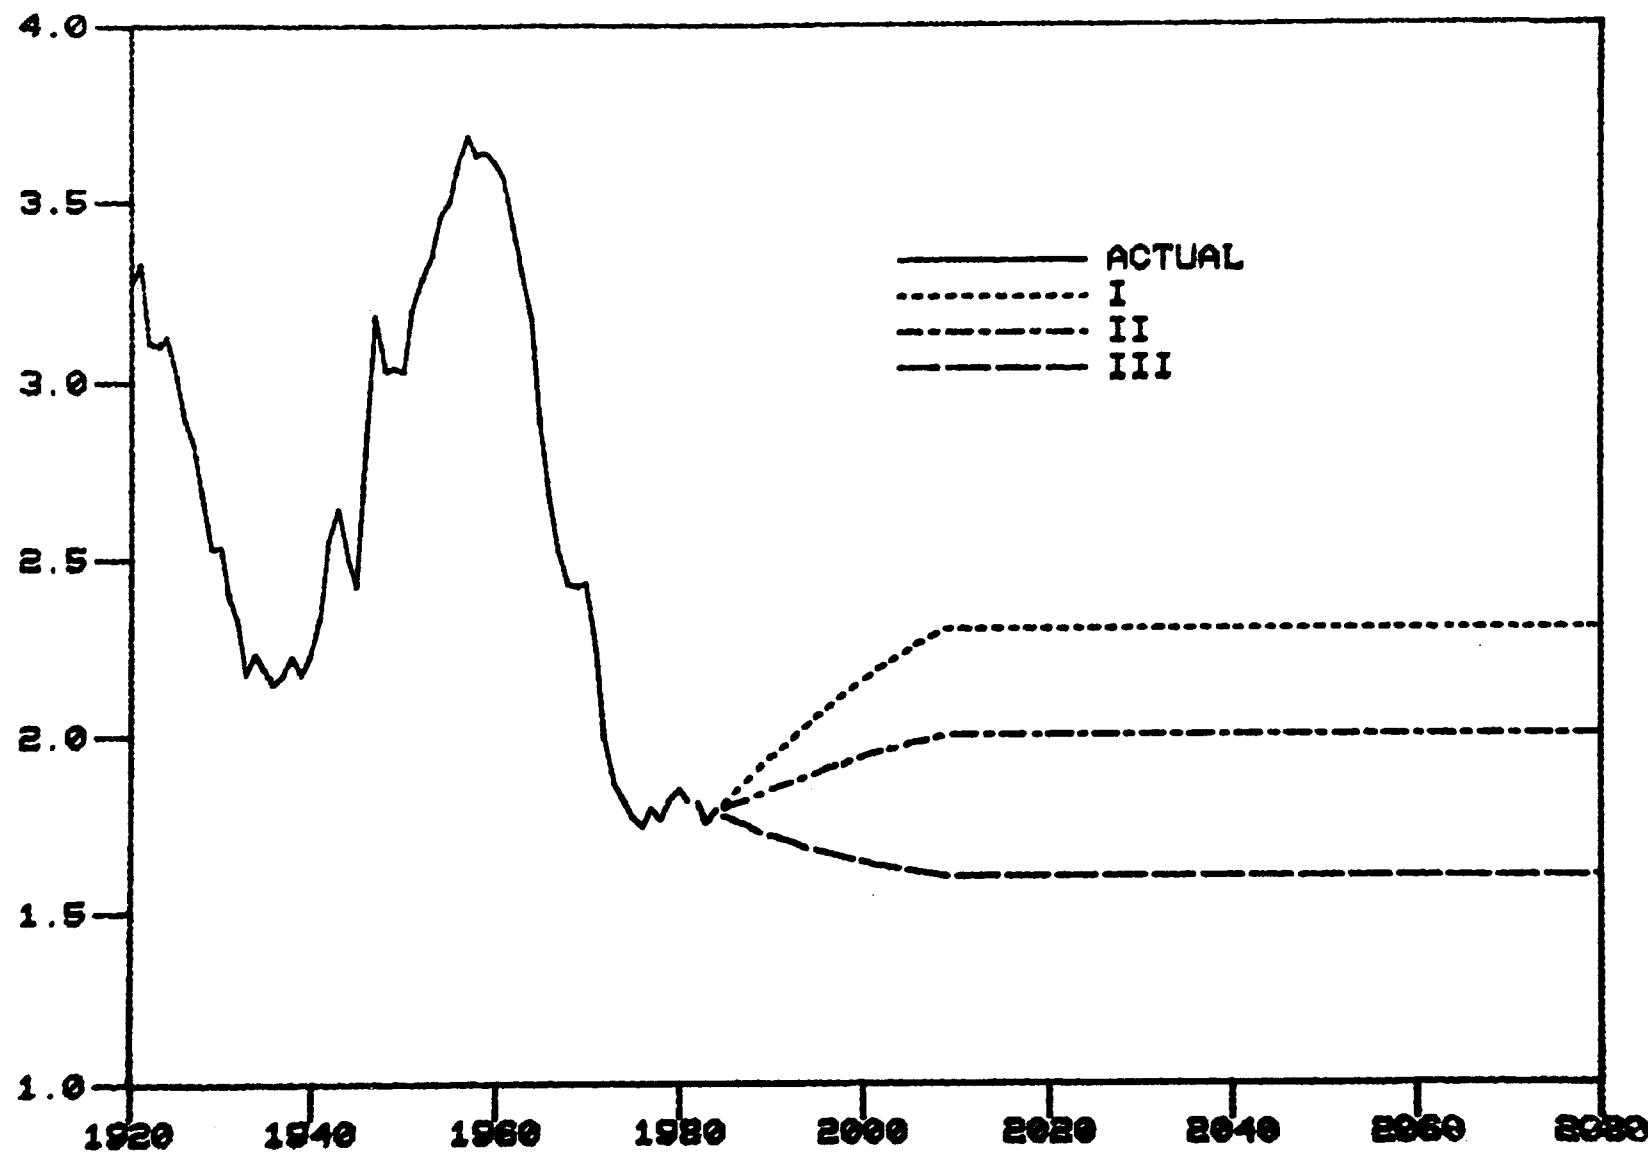

Chart 2a.  
Male Life Expectancy (in years). 1900-2080  
Actual and as Projected under Alternatives I, II, and III

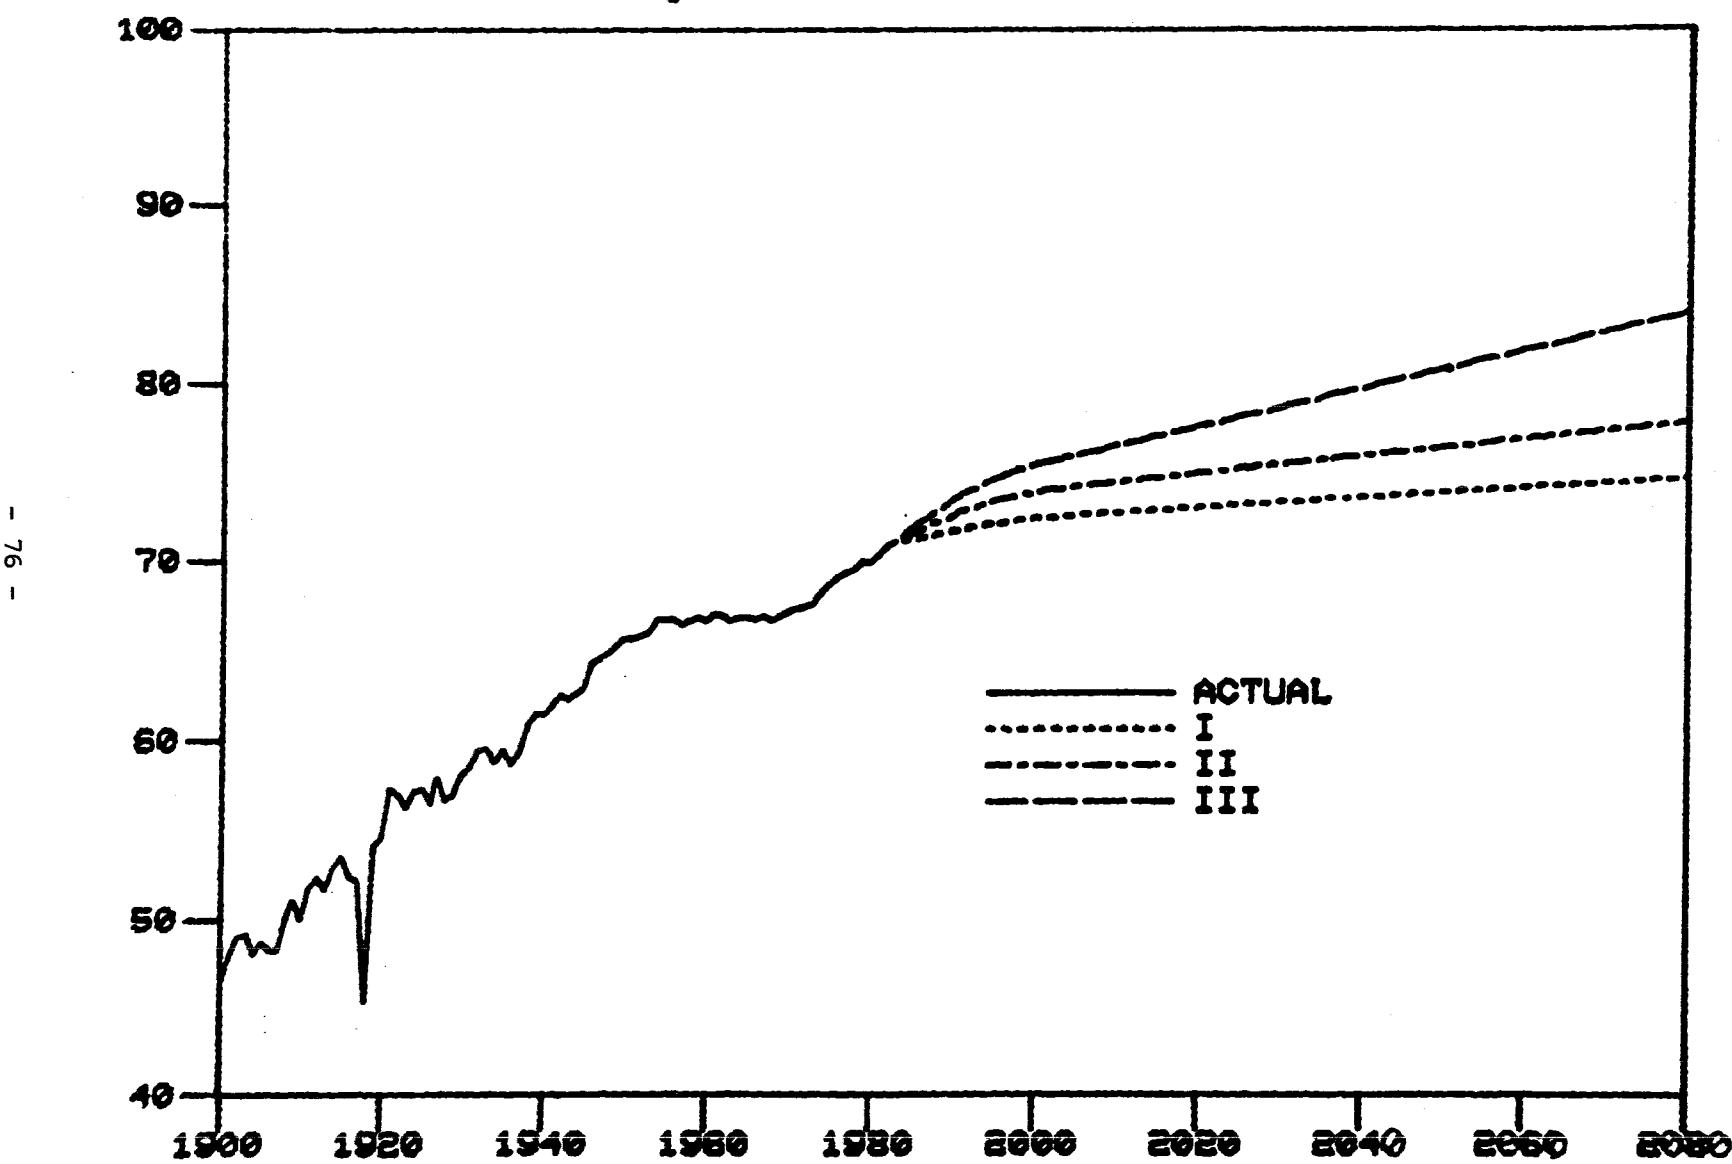

Chart 2b.  
Female Life Expectancy (in years): 1900-2080  
Actual and as Projected under Alternatives I, II, and III

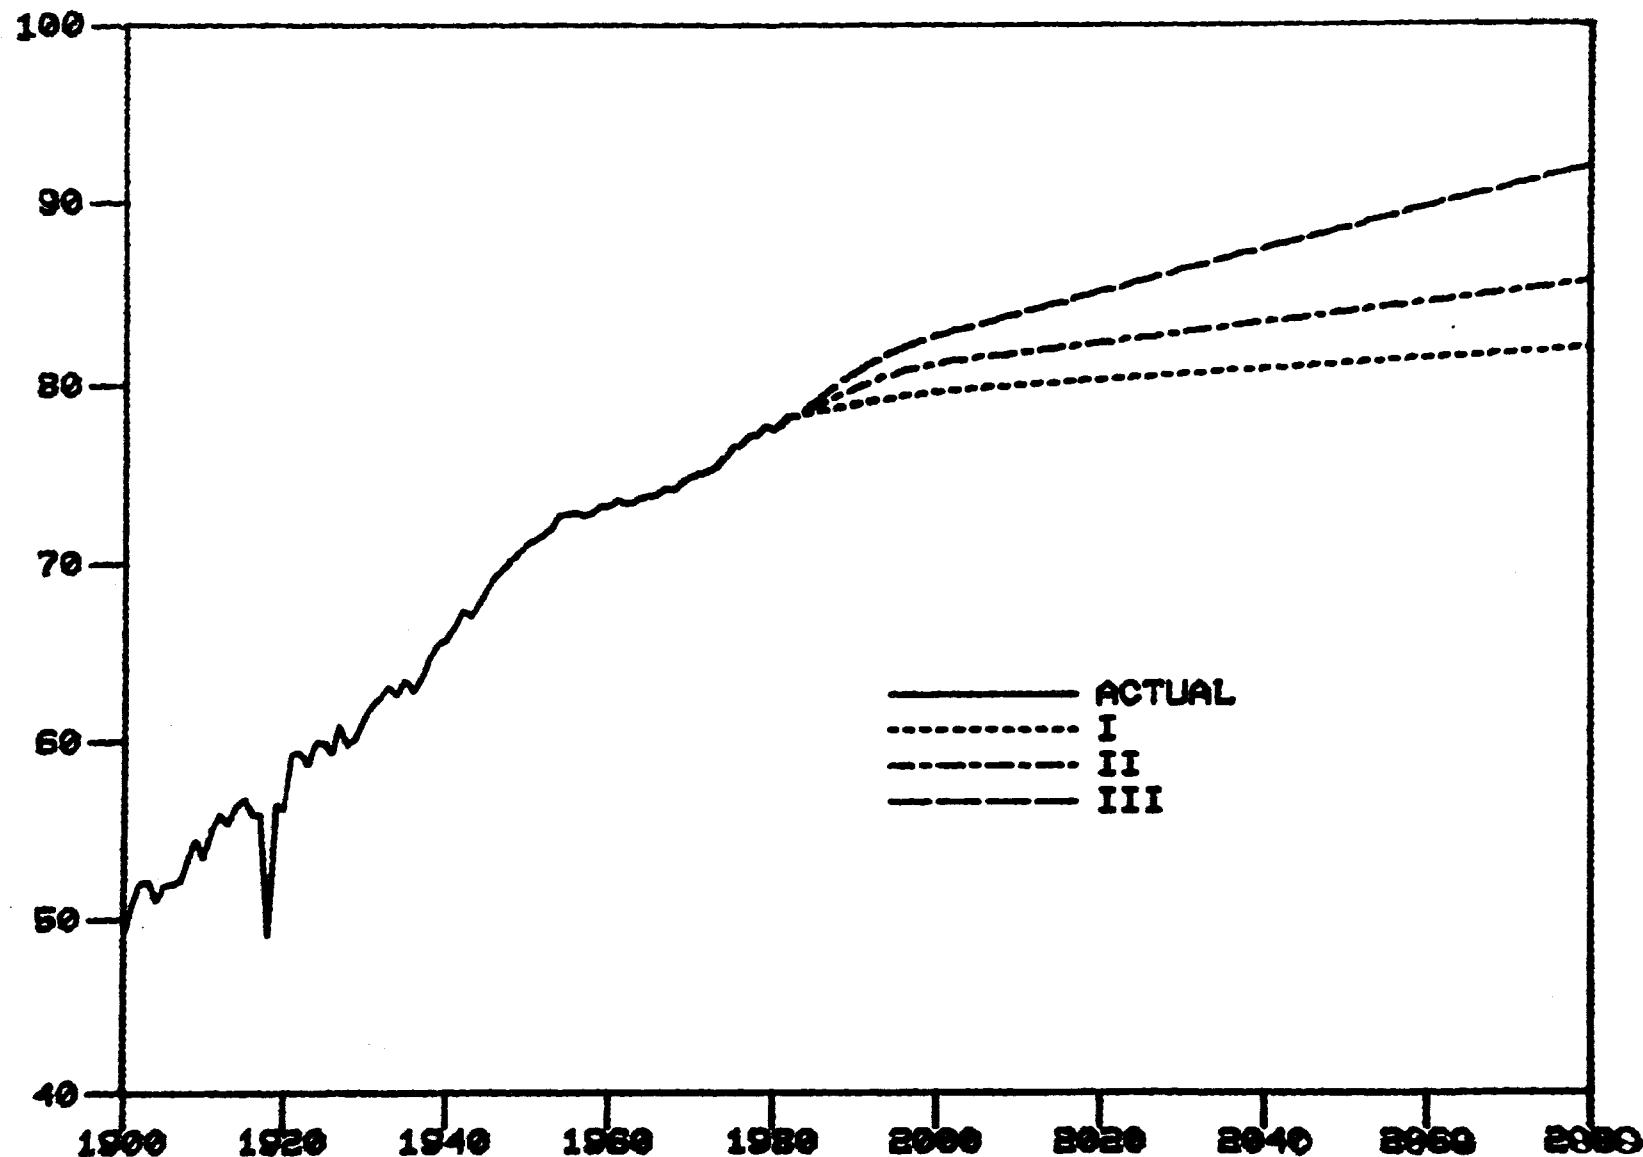

Chart 3.  
Social Security Area Population (in millions), 1960-2080  
Actual and as Projected under Alternatives I, II, and III

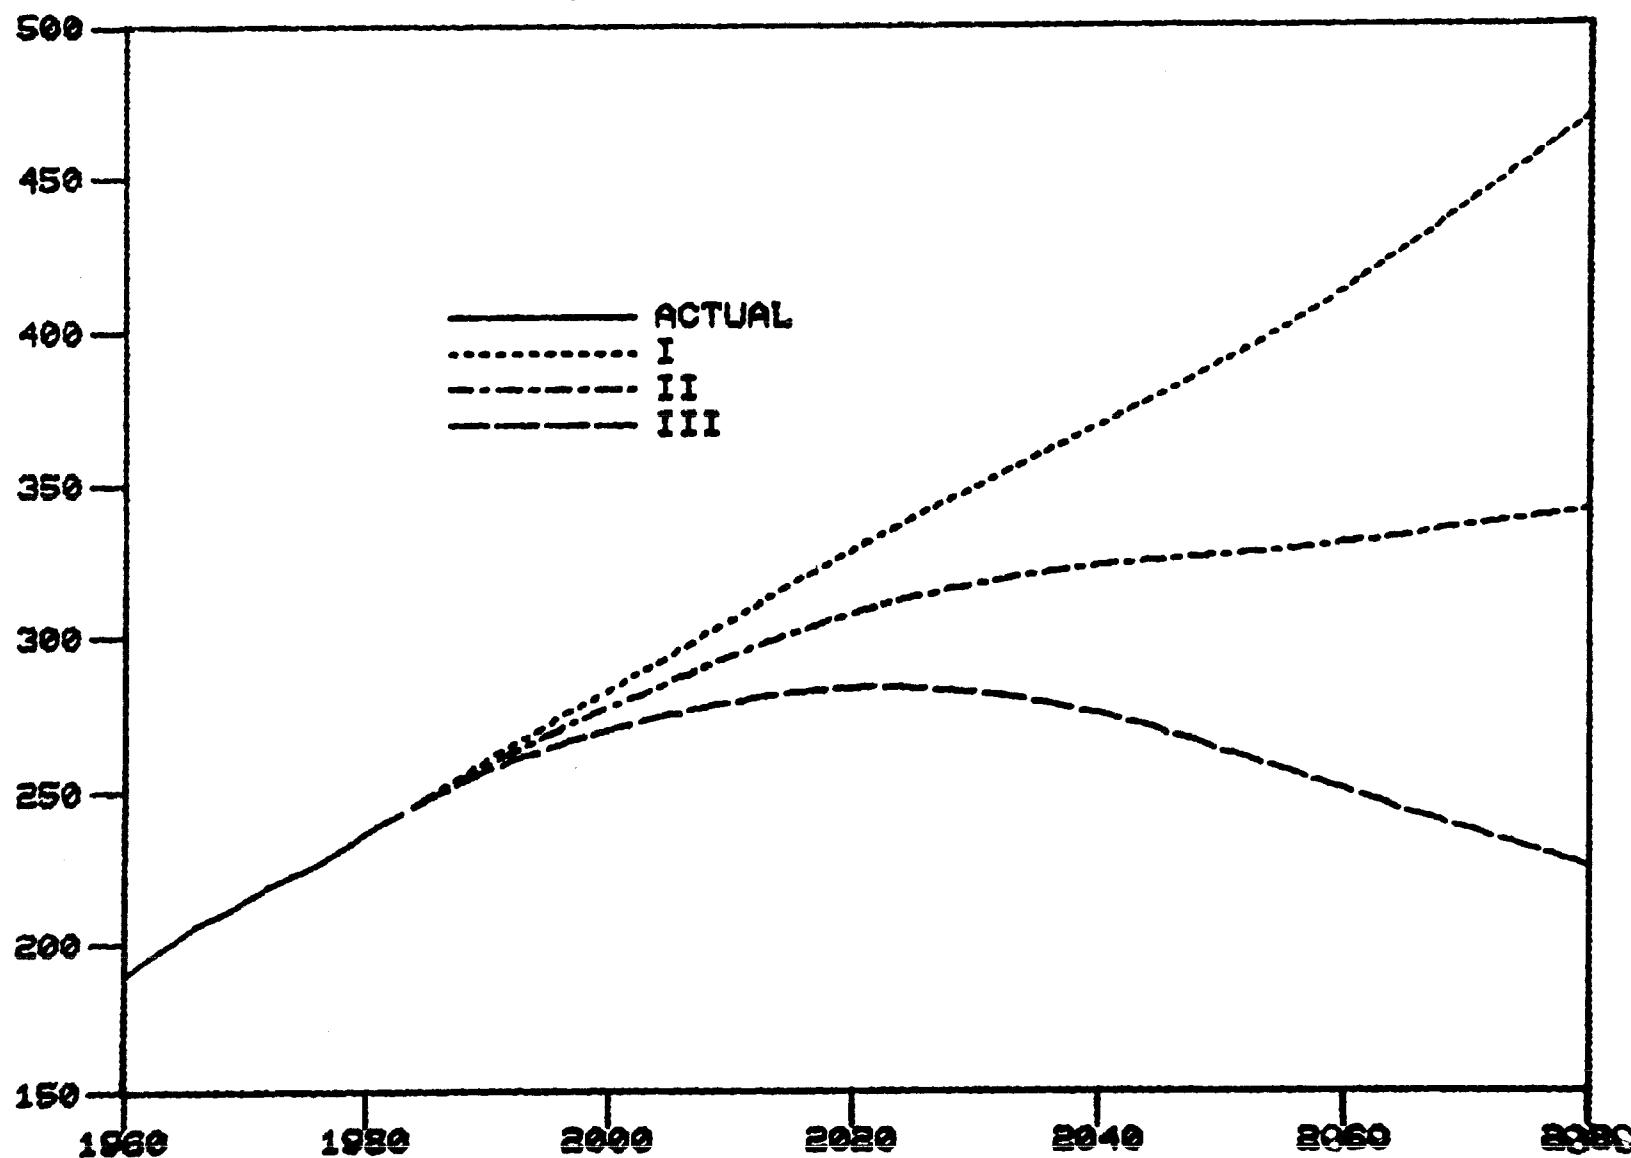

Chart 4.

Social Security Area Population Aged 65+ (in millions): 1980-2080  
Actual and as Projected under Alternatives I, II, and III

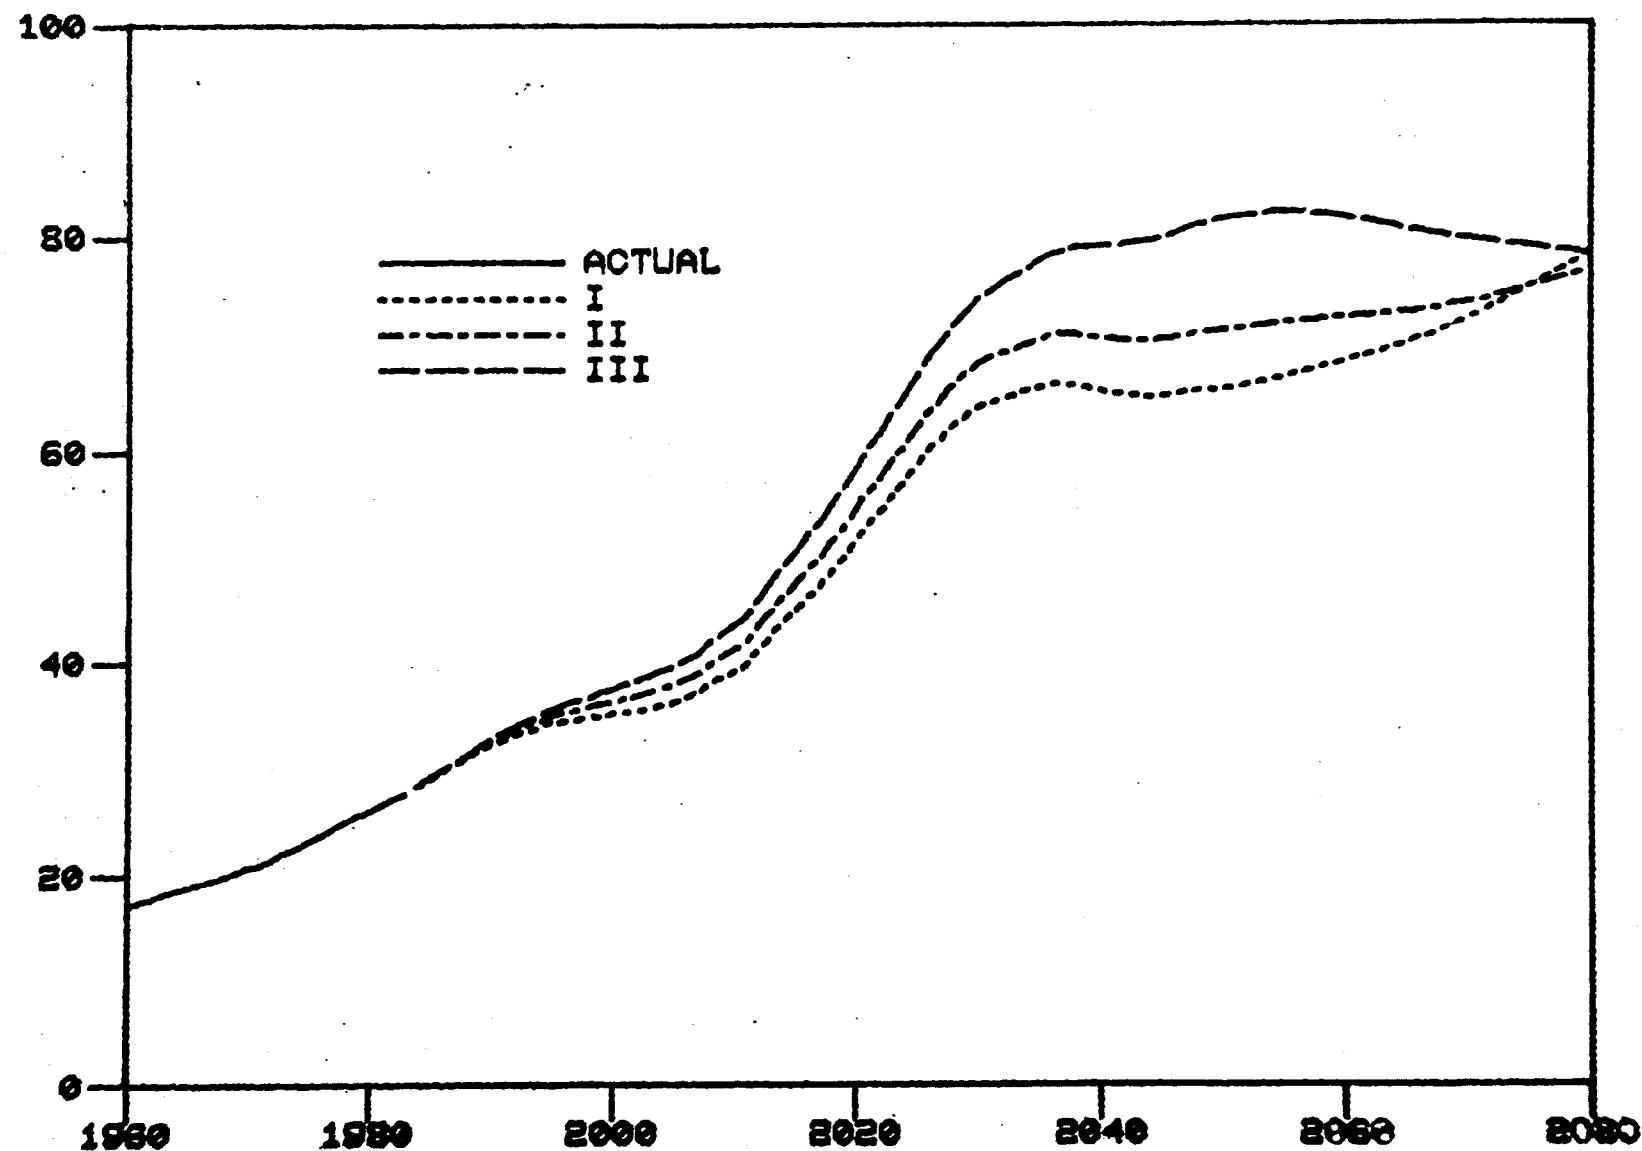

Chart 5.  
Ratio of Population Aged 65+ to Population Aged 20-64. 1960-2080  
Actual and as Projected under Alternatives I, II, and III

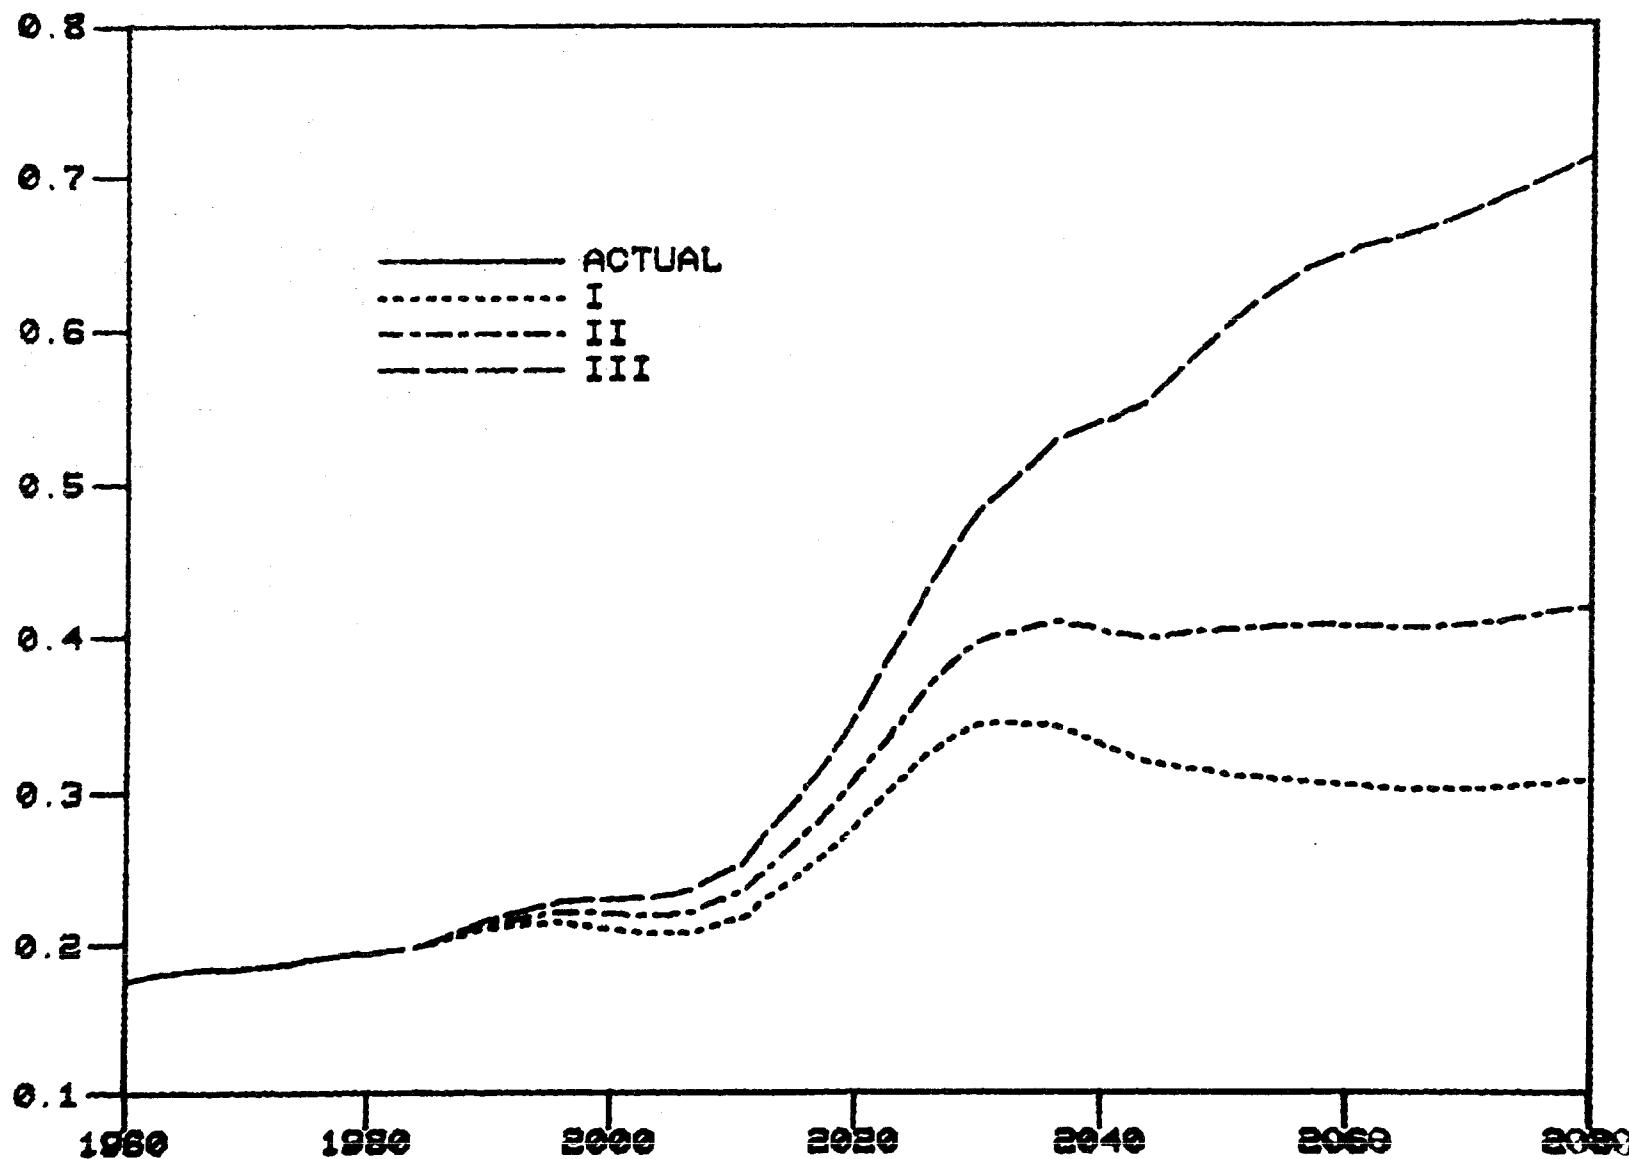

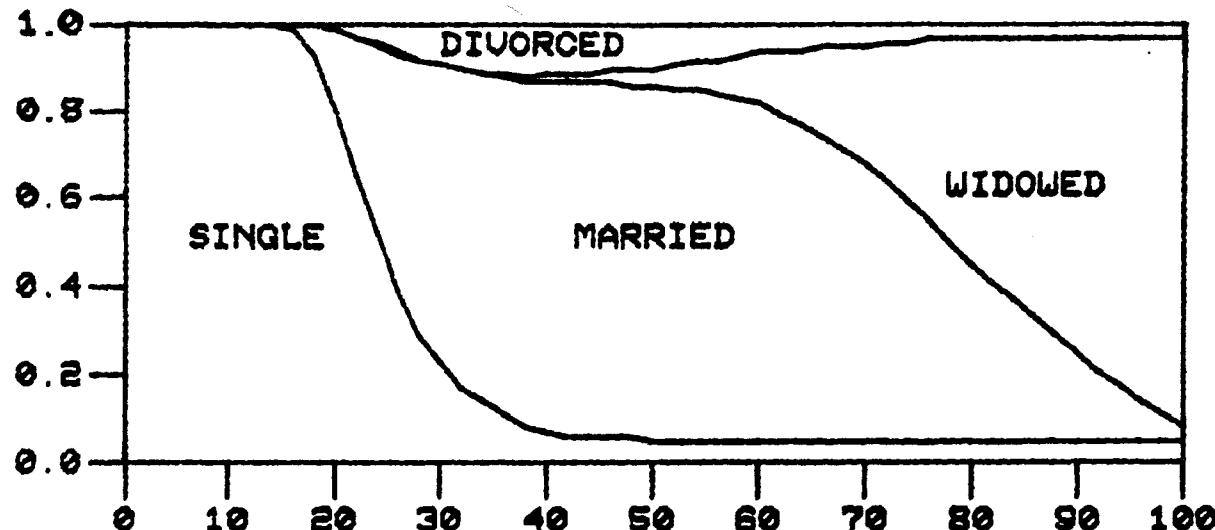

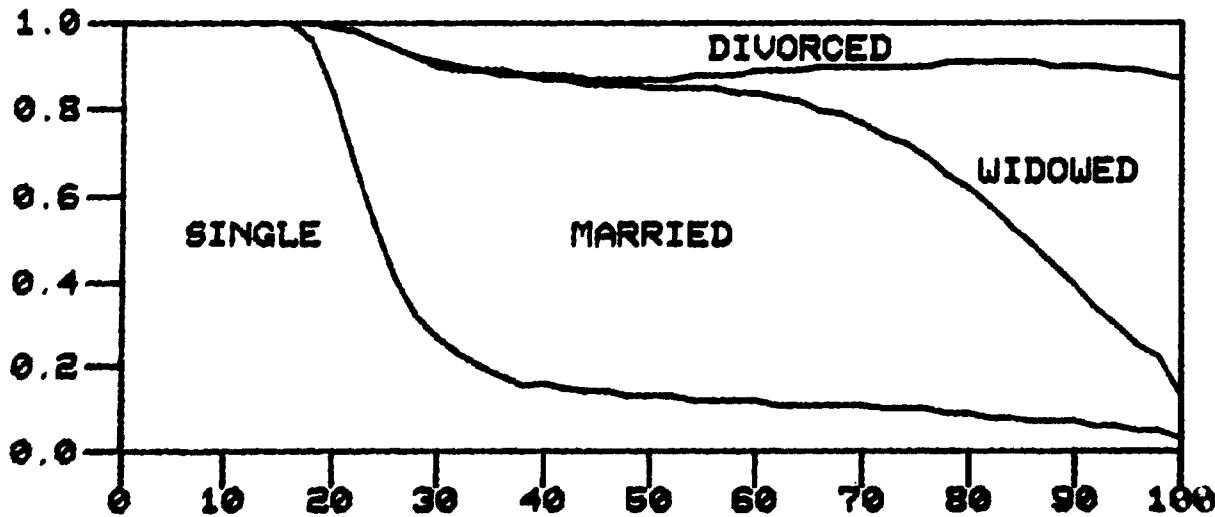

Chart 6.  
Distribution of the Population by Marital Status. Ages 0-100
