FOREWORD

This actuarial study is an update of Actuarial Study Number 94, which was released about 2 years ago. While Actuarial Study Number 94 dealt with the economic projections of the 1984 Trustees Report, the subject here is the economic projections of the 1986 Trustees Report. Newer data are included, methods and assumptions have been slightly modified, but more significantly, the authors have clarified and simplified the presentation of the material.

We continue to welcome comments from readers. The concepts, methods, and data presented are complex and could well admit further simplification. This applies not only with respect to their substance, but also in regard to the presentation.

Francisco R. Bayo
Deputy Chief Actuary

ECONOMIC PROJECTIONS FOR OASDHI COST AND INCOME ESTIMATES: 1986

I. INTRODUCTION

Estimating the long-range financial status of the Old-Age and Survivors Insurance and Disability Insurance (OASDI) Trust Funds and of the Hospital Insurance (HI) Trust Fund requires projection of numerous parameters, which can be classified in three groups: demographic parameters, economic parameters, and programmatic parameters. The purpose of this study is to present and describe, in some detail, the projections of economic parameters utilized in developing the long-range estimates of the financial status of the OASDI and HI programs included in the 1986 Annual Reports of the Boards of Trustees.

The interested reader will find detailed presentations of the projection of demographic and programmatic parameters in recent Actuarial Studies Numbers 97 and 91, respectively. The demographic projections presented in Actuarial Study Number 97, *Social Security Area Population Projections, 1986*, by Alice H. Wade, relate to the estimates included in the 1986 Trustees Report. The programmatic projections presented in Actuarial Study Number 91, *Long-Range Estimates of the Financial Status of the Old-Age, Survivors and Disability Insurance Program, 1983*, by Stephen C. Goss, relate to estimates included in the 1983 Annual Report. The methods used in the 1986 Trustees Report have been changed fairly significantly since 1983 and will be described in detail in upcoming studies.

The economic parameters that are fundamental in the estimation of the financial status of the OASDI program range from those which relate to the total U.S. economy and are thus familiar to almost everyone, such as Gross National Product (GNP), productivity, labor force, unemployment, and earnings and price levels, to those which relate more specifically to the OASDI and HI programs, such as workers in covered employment, average covered earnings, and effective taxable payroll.

Examples of how estimates of the financial status of the OASDI and HI programs depend on these parameters include: (1) the projected number of persons who are insured and eligible to receive benefits each year and its direct relationship to the numbers of covered workers for past years, (2) the average OASDI benefit level for each year and its direct relationship to both the level of average covered earnings and covered worker rates for past years, (3) the level of the unit cost of health services covered by the HI program and its relationship to average employee compensation levels, and (4) the amount of contribution income each year and its direct relationship to the size of the taxable payroll for the year.

Projection of these various economic parameters is accomplished with a combination of assumptions for the most basic parameters and methods utilized to project more involved parameters in relation to the assumed values for the more basic parameters. Recommended assumptions for the most basic parameters are developed by the Office of the Actuary taking into account historical experience, expected future changes in the structure of the economy, and consistency with other assumptions. Final assumptions actually used for the Trustees Report represent the collective judgement of

the Trustees and their staffs and, generally, are quite similar to the recommendations made by the Office of the Actuary. Methods used to project the more involved, or derived, economic parameters are developed primarily on the basis of analysis of historical relationships among parameters, by the Office of the Actuary and the Office of Research, Statistics, and International Policy in the Social Security Administration.

Because none of the parameters used in estimating the long-range financial status of the OASDI program can be projected with certainty, perhaps least of all economic parameters, four separate sets of assumptions were developed for estimates in the 1986 Trustees Report in order to present a range of possible outcomes. These are alternative I, the most optimistic set in terms of impact on the financial status of the OASDI and HI programs; alternatives II-A and II-B, the intermediate sets which differ from each other only in that alternative II-A reflects more rapid economic growth than assumed for alternative II-B; and alternative III, the most pessimistic set of assumptions presented in the 1986 Annual Report.

II. BASIC CONCEPTS

A. Covered Economy versus Total U.S. Economy

Work resulting in earnings that are covered (i.e., totally or partially taxable) under the OASDI (or HI) program comprises the covered economy. Although the covered economy largely overlaps the total U.S. economy, there are significant differences between them. Among the types of work in the total U.S. economy that are not included in the covered economy are some state and local government employment, full-time civilian Federal Government employment for most workers hired before 1984, work performed for some nonprofit institutions prior to 1984 (for HI, only work performed before 1983), and self-employment resulting in annual net earnings of less than \$400. On the other hand, employment of residents of outlying areas¹ and of U.S. citizens working for U.S. companies overseas is included in the covered economy even though it is not part of the U.S. economy.

Naturally, a far more extensive history of basic economic data is available for the U.S. economy than for the covered economy. For this reason, most economic parameters relating to the covered economy are not projected directly but in relation to projections of more widely considered parameters for the U.S. economy. One of the benefits of this approach is that projections of economic parameters for OASDI estimates can be more easily compared with projections made by economists whose focus is the U.S. economy.

B. Economic Parameters Related to the U.S. Economy

The economic parameters for the U.S. economy discussed in this study represent three areas: employment, average earnings, and Gross National Product (GNP).

¹The term 'outlying areas' refers to the areas not normally considered to be part of the United States, such as Puerto Rico, the Virgin Islands, Guam, and American Samoa, but which are covered by the Social Security program.

1. Employment

Every month the Bureau of Labor Statistics (BLS) of the Department of Labor publishes survey-based estimates of total labor-force-participation rates and both total and civilian unemployment rates for the noninstitutionalized U.S. population¹. Annual figures shown in this study are based on the averages of the monthly numbers. The BLS estimates for years prior to 1983 relate to the U.S. population including all armed forces, while estimates for 1983 and later years relate to the population including only those armed forces residing in the U.S.

Because all armed forces are covered under the OASDI program, figures in this study for the U.S. population, the labor force, labor force participation rates, and unemployment rates include all armed forces residing in the U.S. and abroad. The size of the U.S. population by age group and sex on July 1 of years 1947 through 1984 was estimated by the Bureau of the Census and published by the Bureau of Labor Statistics in *Employment and Earnings*. The size of the U.S. population for years 1985 through 2060 was obtained by multiplying the projected Social Security Area population (Table 1) by age-sex specific factors, which were based on the historical relationship between the two populations. Table 2 shows the resulting estimates of the U.S. population for the past and as projected for Alternatives I, II, and III.

For historical years, average total U.S. employment during each year is calculated as the product of the U.S. population on July 1, the average total labor force participation rate (including military residing abroad), and the complement of the average unemployment rate (1.0 minus the unemployment rate). Separate numbers for wage and salary workers and the self-employed add to more than the total, because workers with more than one job may be counted more than once.

The historical numbers of wage and salary workers presented in this study were developed by the Bureau of Economic Analysis (BEA) of the Department of Commerce, based on establishment data compiled by the BLS. Establishment data are collected by surveying employers and thus count "wage items" which represent individual jobs. Because many individuals have more than one wage or salary job at a time, the number of wage items is greater than the total number of persons with some wage or salary employment.

The historical numbers of self-employed persons in this study were developed by the BEA based on the Current Population Survey (CPS), a household survey of individuals which counts an individual as self-employed only if the majority of the individual's hours worked were in self-employment. Some persons counted as self-employed also hold a wage or salary job and are thus counted both as self-employed and as wage and salary workers.

Both household and establishment data are collected monthly and, in general, reflect the number of workers with any work during one selected week in each survey month. The annual employment estimates are calculated

¹In this study, the term "U.S. population" refers to the noninstitutionalized population of the U.S., rather than the resident U.S. population that is most often quoted by the Bureau of the Census.

as the average of the survey-week employment figures for the 12 survey months and thus represent average weekly employment during the year.

Average total weekly U.S. employment during each year, described above, is estimated based on household data and thus includes no multiple counting of workers. A discussion of the development of employment projections is included in Section V., Methods.

2. Average Earnings

Data for aggregate earnings in the U.S. economy are developed by the Bureau of Economic Analysis (BEA) of the Department of Commerce on a quarterly basis. Aggregate earnings are available separately for wage and salary workers and for the self-employed (net proprietors income). Average annual earnings (per worker) are estimated for historical years by dividing the total earnings during each year by the average weekly U.S. employment during the year. As a result, average annual earnings for the total U.S. economy are actually equal to average weekly earnings multiplied by the potential number of paid work weeks for each year and thus reflect an average earnings level for steady employment throughout the year. The potential number of paid work weeks for a given year depends on the number of paychecks receivable, and varies between 52 and 53 for individual workers. The number of paychecks in a given year depends on the exact timing of pay (i.e., Friday vs. Thursday, weekly vs. bi-weekly) and thus may be different for different workers. For this reason, and because variation in the number of weeks per year is not very important when averaging growth rates in average earnings over several years, as is done in our historical analysis, we generally assume 52 potential paid work weeks for each year.

Projections are made for increases in average real earnings and for the CPI separately. A more thorough discussion of the development of average earnings estimates and projections, as well as the related concepts of compensation and productivity, is presented in Section IV., Assumptions.

3. Gross National Product

Analysis of past trends and projection of future levels of the Gross National Product (GNP) are difficult because of the cyclical nature of economic growth. A useful concept for these purposes is the potential real GNP, which is defined as the output in constant dollars that the economy would produce with the existing (or expected) plant and technology under assumed conditions of high but sustainable use of the factors of production—labor, capital, and natural resources. The Council of Economic Advisors has estimated potential real GNP for past years based on (1) an overall civilian unemployment rate that takes into account the changing age and sex distribution of the labor force and has thus changed gradually from 4.0 percent in 1955 to 4.9 percent in 1976, and (2) a manufacturing-capacity-utilization index (as calculated by the Department of Commerce) of 86 percent. With these assumptions, potential real GNP increases in accordance with changes in the size of the labor force, the amount of capital available, and the state of technology, and thus grows relatively smoothly through time.

In order to project potential real GNP, we estimate future changes in the labor force, the average number of hours paid per year, and labor productivity (defined as output per hour paid). In this approach, the labor productivity parameter includes both the capital and technology factors of production.

The primary advantages of the potential GNP concept are that it is relatively easy to project because of its smooth historical trend and that, once projected, it defines the context in which actual GNP is projected. Actual GNP can be estimated for any year in relation to potential GNP based on the assumed levels of the unemployment rate and the manufacturing-capacity-utilization index.

In addition, the use of potential real GNP rather than the actual real GNP as a fundamental concept facilitates consistency of long-range projections for each year's Trustees Report with those for succeeding years. When the economy's position in the business cycle changes significantly from one year to the next, the estimated future levels of potential real GNP are generally affected little, if at all. The change in the economy's position in the business cycle is reflected in the changing ratio of actual to potential GNP. Use of potential real GNP as a fundamental concept assures that the ultimate projected levels of GNP are changed only when changes in underlying assumptions are deemed appropriate.

C. Economic Parameters Related to the OASDI Covered Economy

The most important economic parameters related to the OASDI covered economy are the number of covered workers, their average covered earnings, and the total effective taxable payroll.

1. Covered Workers

The number of covered workers for a calendar year is defined as the number of workers who pay any Social Security taxes for the year. Every year, the Social Security Administration compiles data on the number of covered workers. From these data the coverage rates—defined as the ratio of covered workers during a year to the mid-year Social Security Area population (Table 1)—can be calculated for historical years. These rates are calculated by age group and sex, and are usually expressed in percentages.

Although there are many differences between covered worker rates and labor-force-participation rates, their values in any particular year for each age-sex group are fairly close together. Some differences tend to make covered-worker rates larger. The foremost of these is the fact that workers who are employed for only a part of the year count as covered workers for the whole year but count as labor force participants for only that portion of the year in which they were employed or actively seeking employment. Other differences tend to make covered worker rates lower. The foremost of these is the fact that not all types of employment included in the labor-force statistics are covered by the OASDI program. As shown in tables 11 and 13, higher rates for coverage than for participation have occurred in recent years for age-sex groups with relatively low participation rates, because the effect of partial-year employment tends to predominate in these cases. Lower rates for coverage than for participation occur for age-sex groups with relatively high participa-

tion rates, because the effect of noncovered employment tends to predominate in these cases.

The number of covered workers is projected in relation to projections of other more basic parameters, based on analysis of the historical relationships among these parameters. The basic parameters necessary to project the number of covered workers are projections of the size of the Social Security area population, and the labor-force-participation and unemployment rates for the U.S. economy.

2. Average Covered Earnings

Differences between the rates of increase in average covered earnings and average earnings in the total U.S. economy have been small, even though the methods of computing the averages are quite different. Average-covered-earnings estimates are based on actual data for all workers in OASDI covered employment and reflect the average annual earnings for persons with any covered employment during the year. Average earnings for the total U.S. economy, on the other hand, are based on separate survey estimates of the number of workers and the amount of aggregate earnings. The fact that the number of workers in the U.S. economy is actually calculated as average weekly U.S. employment during the year (see Section II.B.) means that average U.S. earnings is actually calculated as average weekly earnings multiplied by 52 (see Section II.B.2.). Fortunately, these differences do not appear to have a large effect on the rates of increase in the measures of average covered earnings versus average total earnings.

An additional factor which has contributed to the difference between the rates of increase in average covered versus average total earnings is the historical trend by the OASDI program towards covering an increasing percentage of workers in the total U.S. economy. This trend will continue and is reflected in the average OASDI covered earnings, which are projected to increase slightly faster over the next 30 years, as the Federal civilian employees (who have a somewhat higher-than-average level of annual earnings) gradually become covered¹.

OASDI covered self-employment income (covered SEI), as used in this study, means total net earnings from covered self-employment excluding such earnings for any individual that total less than \$400 for the year. This definition of covered SEI differs from that used in the Social Security Act where SEI also reflects the effect of the earnings base. In this study, the quantity that results from applying earnings-base limitations to covered SEI is referred to as taxable SEI.

Increases in average covered earnings are projected in relation to projected increases in average earnings for the U.S. economy, taking into account any changes in the types of work included in the OASDI covered economy. Projected increases in average real covered earnings are made separately from those pertaining to the CPI. A more thorough discussion of the projection of average covered earnings is included in Section IV.B.

3. Effective Taxable Payroll

One of the most important results of the economic projections is the "effective taxable payroll," which is

¹The Social Security Amendments of 1983 provide that Federal civilian employees hired after 1983 are covered under the OASDI program.

defined as the theoretical amount which when multiplied by the combined employee-employer OASDI (or HI) tax rate yields the actual (or projected) tax liability for the year. In presenting long-range estimates of the financial status of the OASDI (or HI) program, both the cost and income rates expressed as percentages of effective taxable payroll can be directly compared with the OASDI (or HI) tax rates with which everyone is familiar. In addition, this practice maintains a perspective on the size of the program that might be lost if cost and income estimates were expressed in terms of the inflated dollar amounts anticipated for 25, 50, and 75 years into the future.

Effective taxable payroll consists of total earnings which are subject to OASDI (or HI) taxation, including deemed military-service wage credits starting 1984, but, in the case of OASDI payroll only, not including earnings of railroad workers, for whom accrued OASDI tax and benefit amounts are transacted on a net basis each year between the Social Security Administration and the Railroad Retirement Board. These total covered earnings are adjusted to reflect the maximum amount taxable per worker each year and the fact that a lower effective tax rate than the combined employee-employer tax rate applies to income from tips and multi-employer excess wages¹, and to self-employment income for years prior to 1984.

Starting in 1984, the OASDI Trust Funds receive income not only from taxation of earnings but also in the form of revenue transfers from the general fund of the U.S. Treasury in amounts equal to the additional federal income taxes paid because of taxation of up to one-half of OASDI benefits. The amounts of these transfers are presented in the Trustees Report as percentages of effective taxable payroll, as is done with respect to the costs of the program. A discussion of the projection of effective taxable payroll is included in Section V.E.

III. OVERVIEW OF PROJECTION

The purpose of this section is to provide the reader with a general understanding of the interrelationships among all the economic parameters considered in this study. In particular, this section outlines the flow of development from one parameter to the next, when viewed from the perspective of projecting future values for each of these parameters.

The culminating economic parameter in this study is effective taxable payroll. Projection of effective taxable payroll requires prior consideration of all the other economic parameters. On the other hand, labor productivity, most often referred to simply as productivity, is one of the initial, or most basic, economic parameters considered in this study. Assumptions about future changes in productivity represent the starting point for development of projections for many of the other parameters in our model. Productivity will be discussed in detail in Section IV., Assumptions.

Projection of all the economic parameters required for estimating the financial status of the OASDI (and

¹When a worker has more than one job, each employer must pay OASDI tax on earnings up to the taxable maximum amount, while the worker pays tax on his or her combined total earnings only to the maximum.

HI) program requires two separate tracks of development. The first of these begins with the productivity assumption and yields projections of aggregate values for potential and actual GNP, and is thus referred to as the "aggregate method." The aggregate method ultimately yields projections of effective taxable payroll through the application of a series of linkages between GNP and payroll.

The second track of development also begins with the productivity assumption and then yields projections for the average levels of earnings for workers in the total U.S. economy and for those in OASDI (or HI) covered employment, and is thus referred to as the "average method." The average method also ultimately yields projections of effective taxable payroll.

The aggregate and average methods are equivalent in the sense that they both utilize the same assumptions and yield consistent results. The need for two tracks of development lies in the need for a wide variety of economic projections. The charts on pages 8 and 9 illustrate the progression of development of parameters in each track. Entries in these charts represent projected rates of change in the various parameters which are, in general, developed in advance of, and provide the basis for, calculation of the levels of the parameters.

The solid line boxes identify the more basic parameters, while the dotted line boxes identify the more involved or derived parameters. Numbers in parentheses next to the parameters indicate table references where projected values can be found. The specific development of each derived parameter is discussed in Section V., Methods. A description of the basis for assuming values for the more basic assumptions is provided in Section IV., Assumptions.

IV. ASSUMPTIONS

The first phase of development of economic projections for the purpose of estimating the financial status of the Social Security programs is the identification of basic parameters and the selection of assumed future values for those parameters. In our analysis, we attempt to subdivide parameters into the most basic elements for which high quality data are available.

In some cases, a parameter may be treated both as a basic parameter, for which assumed future values must be adopted based on analysis of historical values and expected future trends, and as a more complex, or derived, parameter, for which projected values are based on the already assumed or projected values for two or more other economic parameters. An example of this type of parameter is average real earnings. Because average real earnings for OASDI covered workers is such a fundamental parameter in the projection of both future income and future benefits, selection of future values is based on both direct analysis of historical average earnings data and on the development of assumptions for productivity and other basic parameters.

Assumed values for basic parameters are developed for three separate periods covering the next 75 years. For each of the next 10 years, values are selected which reflect, to a considerable extent, recent experience, cycles, and trends through the first several years and a movement toward the assumed ultimate value thereaf-

ter. Assumed ultimate values represent the expected average level of a parameter that is consistent with the underlying nature of the set of assumptions being developed: optimistic (I), intermediate (II-A and II-B), or pessimistic (III). Many parameters are assumed to reach their ultimate values within the first 10 years, while others may not do so until 20 or 30 years into the future. The last assumption to be adopted refers to the transition period between the tenth year and the first year for which the ultimate assumption applies. Values for the transition period are generally chosen to produce a path that approaches the ultimate assumption smoothly.

When setting ultimate assumptions, analysis of historical data must encompass a reasonably long period of time. The values of economic parameters often fluctuate significantly from one year to the next as the economy moves through business cycles. In addition, several business cycles often take place within one longer term cycle or trend. The economic experience during specific phases of the cycles and trends can be significantly better or worse than the average over an extended period. For these reasons, we analyze the experience of selected economic parameters at least as far back as the early 1950's, to include favorable as well as unfavorable trends. Thus, although recent experience is important in establishing a starting point and the current trend for the projections, this should not be allowed to influence too heavily the choice of ultimate values.

Generally, we pay less attention to data for years prior to the early 1950's. The national economy was overwhelmed during the 1930's and 1940's first by the "Great Depression" and subsequently by World War II and the post-war recovery. Although we recognize the possibility of either an extended depression or a world war in the future, neither of these events is consistent with any of the alternative sets of assumptions developed for the Trustees Report.

The experience of the 1950's and 1960's provides an example of a period when the economy operated very favorably through several business cycles. The U.S. economy was left essentially intact in the wake of World War II and expanded rapidly in order to fill both domestic and foreign demand, with little competition from the war-ravaged nations of Europe and Asia. Inflation (as measured by the CPI-W) was low, averaging only 1.9 percent per year between 1951 and 1969, while productivity grew rapidly, averaging 2.5 percent per year.

On the other hand, the experience of more recent years has been very unfavorable. Inflation averaged 7.1 percent per year from 1969 to 1984, while productivity increased at an average annual rate of only 1.5 percent. Development of ultimate assumptions is based both on thorough analysis of this kind of data, and on expectations of future trends and conditions which may be quite different from those of the past.

A. Productivity

The productivity parameter is one of the first and most basic elements of both the aggregate method and the average method discussed in the previous section. Productivity, sometimes called labor productivity, is

defined as the ratio of the total value of production (as measured by the real GNP) to the total number of hours of paid work. Production is measured in real terms (e.g., GNP in 1972 dollars) with the primary focus on annual percentage increase in productivity instead of on the absolute value of the ratio for each year. The number of hours of paid work includes paid vacation and sick time, and also includes some hours worked by unpaid family members.

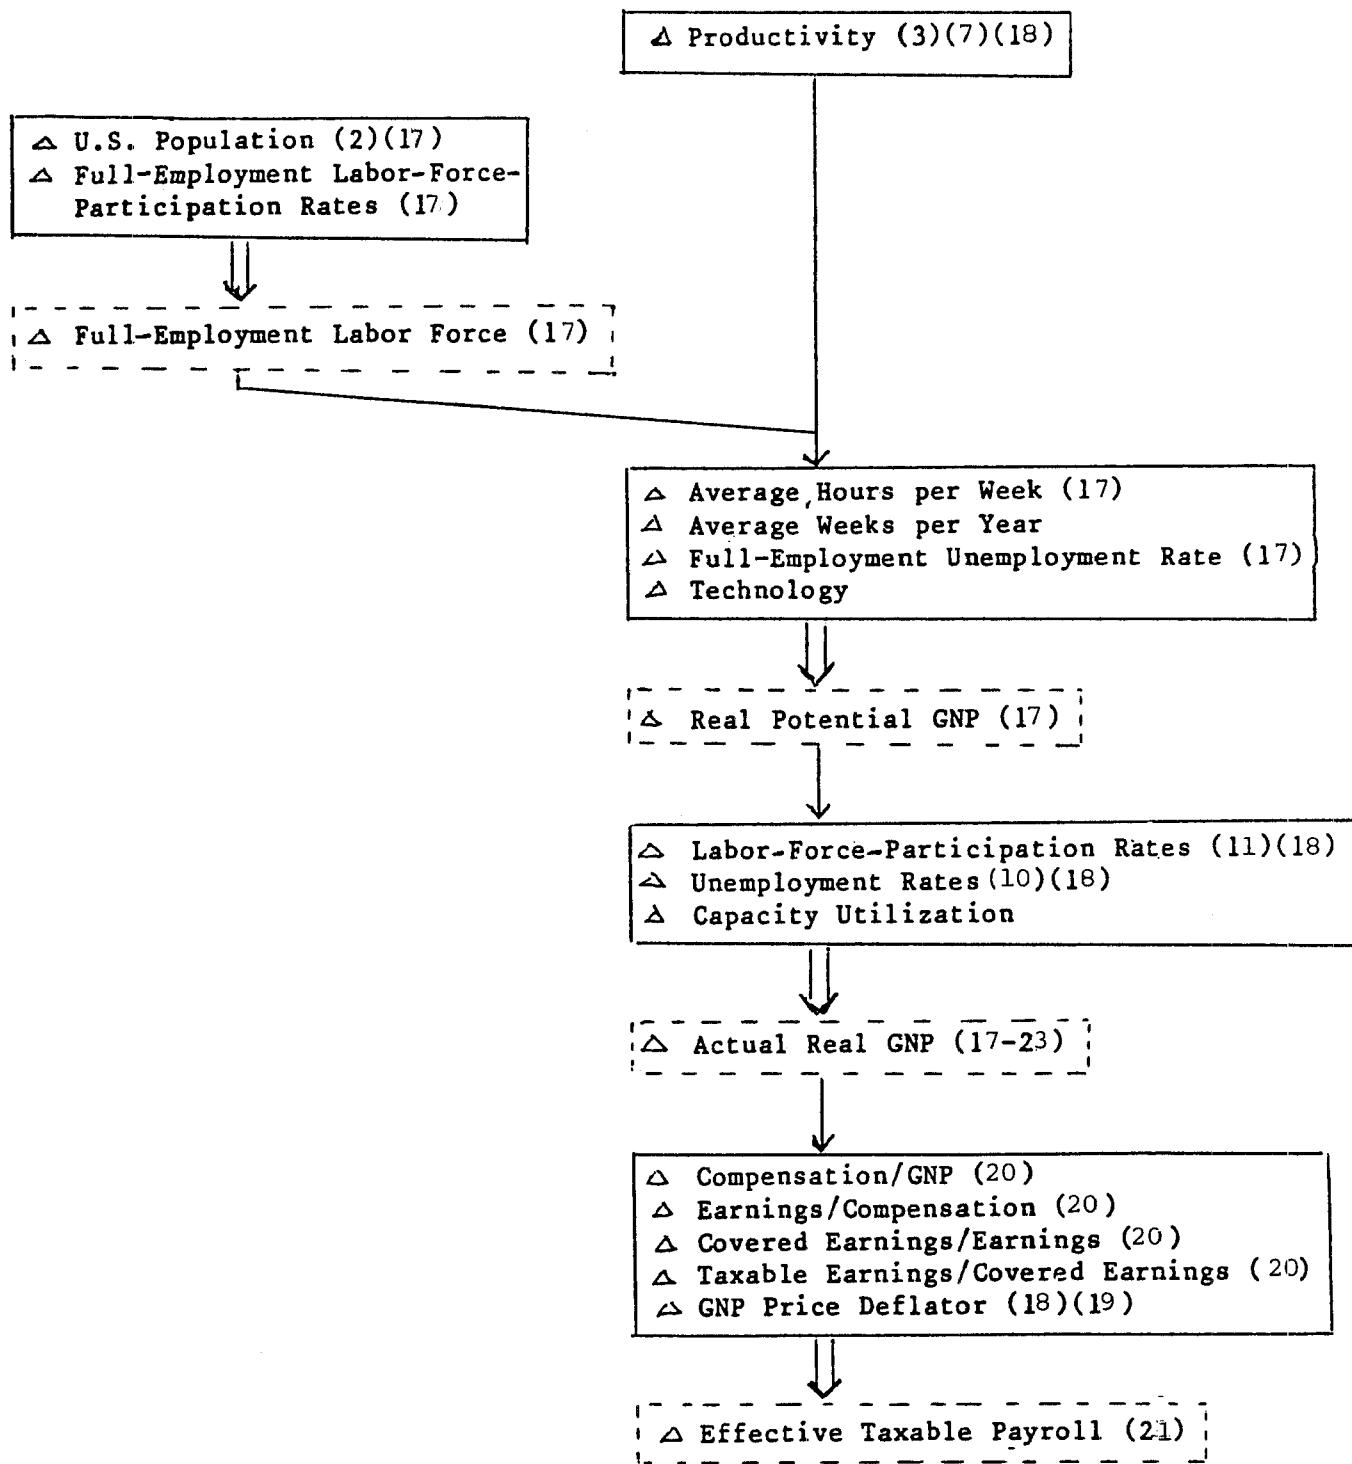

The ultimate assumed rate of increase in productivity is developed largely on the basis of analysis of historical productivity experience combined with a qualitative assessment of future influences. This analysis is the subject of the balance of this section. For a description of the method by which productivity increases are projected between the historical period prior to 1985 and the ultimate period after 2015, see section V.C., Potential (Real) GNP.

Historical productivity data are most widely available for the "private nonfarm business sector" as defined by the Bureau of Labor Statistics (BLS). However productivity assumptions for the 1986 Trustees Report presented in this study were based on analysis of the index of productivity for the total U.S. economy, which has more recently become available to us from the BLS. We believe that the index for the total U.S. economy is more appropriate for our purposes, because it is more in line with the OASDI (and HI) coverage. This newer measure of productivity, which refers to all types of workers, including government workers, who represent a significant proportion of the U.S. workforce and a growing proportion of the OASDI covered workforce, is more complete and useful, because the productivity parameter is utilized in both our aggregate and average methods to represent productivity for the total U.S. economy.

Productivity for the private nonfarm business sector rose at an average annual rate of 1.90 percent during the 30-year period 1954-84. On the other hand, productivity for the total U.S. economy rose at an average annual rate of 1.96 percent over the same period. The experience over the last 10 years of historical data (1974-84) was quite unfavorable, with average annual productivity changes of only 1.35 percent and 1.28 percent, according to the indexes for the private nonfarm business sector and the total U.S., respectively; while the increases over the prior 20 years (1954-74) were very favorable—2.18 percent and 2.31 percent, respectively.

The Trustees' assumptions of future productivity increases (summarized in table 7A) reflect the belief that the very bad experience of the past 10 years does not foretell the future. Several conditions have prevailed over the past 10 years, significantly affecting productivity, which will not generally exist in the future. These include the rapid acceleration of production costs related to new environmental and safety regulations, highly significant increases in the cost of energy, a great influx of new, inexperienced workers as more women choose to enter (or reenter) the labor force at the same time that the baby-boom generation reached working age, and rapidly aging plant and equipment.

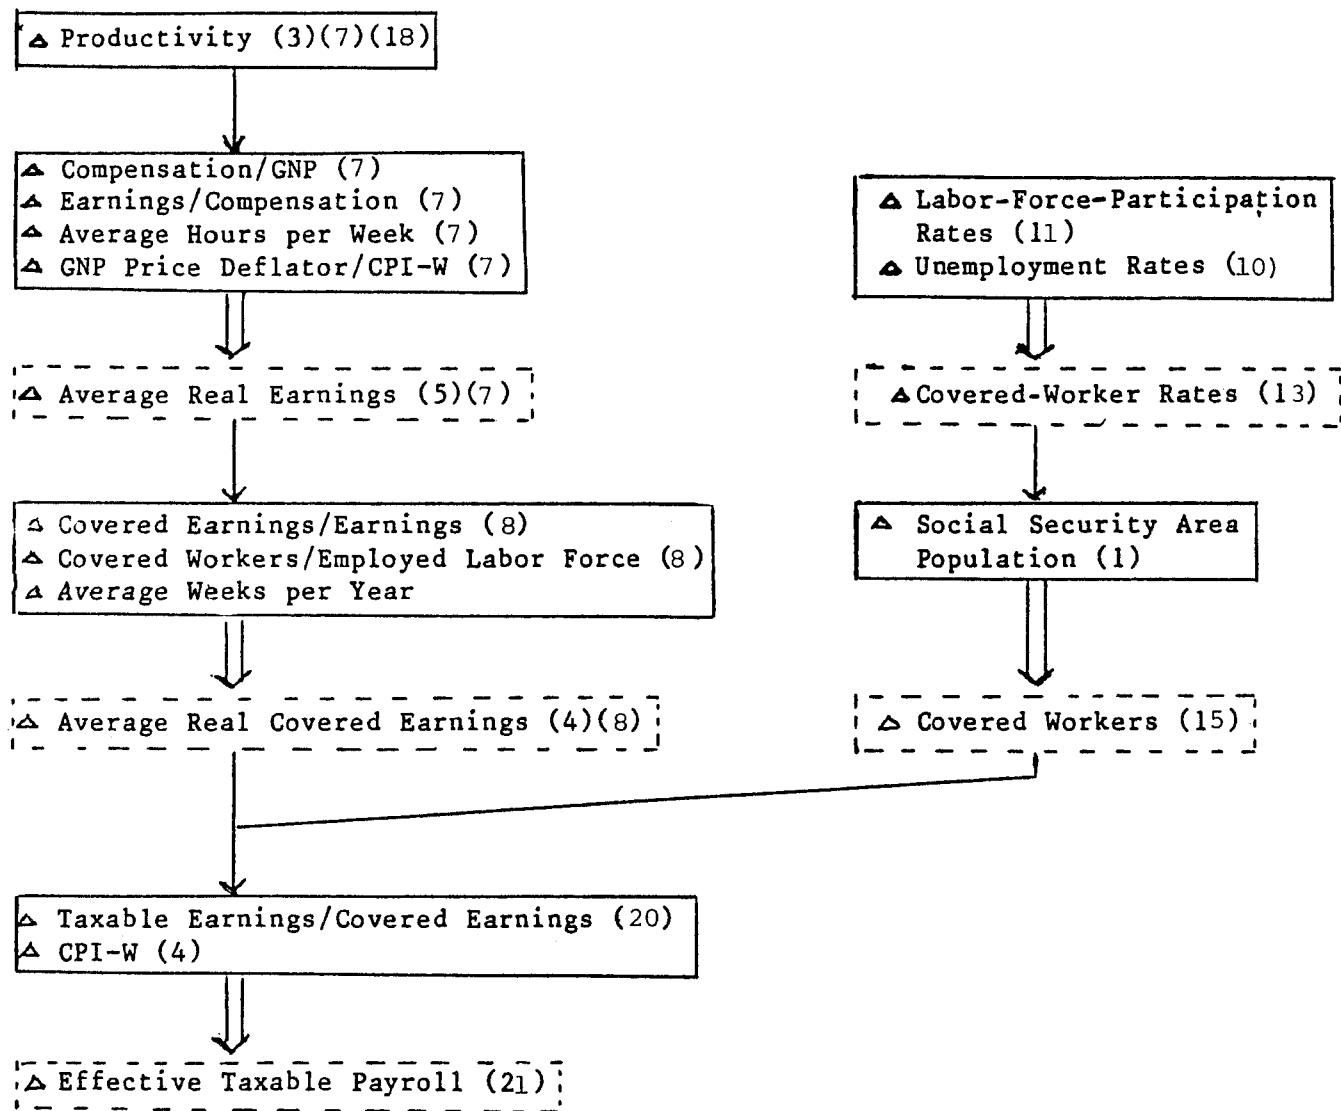

Development of Projected Annual Changes in
Economic Parameters: Aggregate Method

NOTE: The numbers in parentheses are table references, and the symbols should be interpreted as follows:

- $\underline{\quad}$: derived parameters

Development of Annual Changes in
Economic Parameters: Average Method

NOTE: The numbers in parentheses are table references, and the symbols should be interpreted as follows:

- " Δ ": annual percent changes
- " \downarrow ": the combination of the preceding and the following
- " \Downarrow ": the preceding yields the following
- : basic parameters
- : derived parameters

However, it is not expected that productivity over the long-term future will return to the high post-World War II levels of the 1950's and 1960's. Only the optimistic assumption (alternative I) reflects productivity increases of that level. The assumed ultimate productivity increase for the intermediate (alternative II-B) set is at about the same level as the average for 1954-84.

In addition to projecting productivity increases for all workers in the U.S. economy, we have attempted to measure separately the past and projected future increases in productivity for wage and salary workers, and for the self-employed (proprietors and partners). In order to separate historical total productivity in this way, we: (1) obtained separate counts of hours worked by self-employed persons from the BLS, and (2) computed the portion of the GNP that is attributable to the self-employed using data in the National Income and Product Accounts (NIPA). Separate analysis of productivity for the wage and salary workers and the self-employed facilitates separate analysis of average earnings increases for these two groups. For the 1986 Trustees Report, ultimate increases in productivity were assumed to be the same for the wage and salary workers and the self-employed.

Tables 3A, 3B, 3C, and 3D present historical increases in productivity indexes for the total U.S. economy, the private nonfarm business sector, and the wage-and-salary and the self-employed components of the total U.S. economy. Tables 7A, 7B, and 7C summarize both past and assumed future rates of increase in productivity for the total U.S. economy, wage and salary workers, and the self-employed, respectively.

The reader may notice that the assumed ultimate rates of productivity increase are not necessarily even, round values. Assumed productivity increases must be consistent with assumed increases in average real earnings, and with the linkages between productivity and earnings. Although we consider productivity to be the most fundamental economic parameter from a theoretical perspective, the assumed rates of increase in average real earnings more directly influence the financial status of the OASDI (and HI) system, and, as a result, are more frequently cited in this context. Therefore, increases in average real earnings (specifically, the real-wage differential) are projected in round, even rates for the purpose of easy citation, and productivity increases are assumed to take on uneven values so that consistency is maintained.

B. Average Real Earnings

Two different analyses are used to aid in the projection of the annual increases in average real earnings. The first is a direct analysis of the past annual increases in average real covered earnings. The second is an examination of experience on productivity, average real earnings, and the linkages between the two for the total U.S. economy. This is followed by an examination of the relationship between earnings in the U.S. economy and covered earnings. Although our primary goal is the analysis of average earnings for all workers, a subdivision into earnings of wage and salary workers and earnings of the self-employed provides additional insights into historical data and facilitates projection of future values.

1. Direct Analysis

Tables 4A, 4C, and 4D show historical average real OASDI covered earnings (indexed to 1967 by the CPI-W) for all workers, wage and salary workers, and the self-employed, respectively, along with the average annual increases over selected intervals. The annual increase in average real earnings has fluctuated between 5.13 percent in 1953 and -4.72 percent in 1980. The moving averages shown in Table 4A reveal that the general trend since the mid-1960's has been downward. Few analysts believe that the future trend of average real earnings will be to continue downward, or even to level off at the current low level. A significant increase in average real covered earnings has already been registered for 1983 and 1984.

Many factors have affected average real earnings in the past and can be expected to affect average real covered earnings in the future. It is difficult to enumerate all of these factors and even more difficult to quantify their effects. We have quantified the effects of the changing age-sex composition of covered workers, albeit imperfectly. Because average earnings vary by age and sex, a change in the composition of the workforce affects the average for all workers combined. Table 4B shows the annual increases in average real covered earnings, age-sex adjusted according to the age-sex distribution of covered workers in 1970. Thus, Table 4B is a modification of Table 4A that permits us to quantify the effects of the changing age-sex composition of covered workers on average real earnings for all workers combined.

The average real earnings level for each specific age-sex group is the same in Table 4B as in Table 4A, but for each year the weighting of each age-sex group in Table 4B is the number of covered workers in 1970, while the weighting in Table 4A is the number of covered workers for the specified year. Estimates of average earnings by age and sex are based on median earnings data available through 1979. Age-sex relative earnings levels are assumed to remain constant after 1979 for Table 6. The analysis shows that since 1951, the changing composition of the workforce has had a dampening effect on increases in average real earnings. The average annual increase over the 30-year period 1954-84 was 1.02 percent, but it was 1.12 percent on the age-sex adjusted basis. It also shows that this demographic effect on average real earnings has recently reversed. Our analysis, based on the expected future age-sex distribution of covered workers, shows that there will be a favorable trend from now until 1995, adding roughly 0.5 percent to the annual increase in average real earnings, and that after 1995, the demographic effects should be of little consequence.

This demographic labor force composition effect (which has depressed the growth in average real earnings in the past but will likely aid in its growth in the near future) is the result of the increasing labor-force participation of women and the movement through the various working ages of the large baby-boom generation. Past increases in the labor force participation of women and the coming of working age by the baby-boom generation have introduced large numbers of inexperienced workers, thus bringing down the average earnings level. As the increases in the labor-force-

participation rates for women decelerate, the depressing effect of the earlier rapid increases on average real earnings will diminish. Average real earnings have also been depressed while the baby-boom generation was entering the labor force, but will be enhanced as the baby-boom generation reaches the age of prime earning power.

2. Analysis in Relation to Productivity

Because, over a long period of time, increases in average real earnings are only possible if productivity increases, our second analysis of annual increase in average real earnings is based on the analysis of the productivity of workers and of the linkages between their productivity and their average real earnings. Because productivity and related data are available for the total U.S. economy, but not for the OASDI covered economy, this analysis is done in two stages. First we analyze the historical relationship between productivity and average real earnings in the U.S. economy, and then we examine the relationship between average real earnings in the U.S. economy and average real earnings of OASDI covered workers.

a. Productivity and average earnings in the U.S. economy

The relationship between productivity (production per hour paid) and average real earnings for the U.S. economy¹ can be summarized in the following formula:

$$\begin{aligned} & (\text{Production/Hour}) \times (\text{Compensation/Production}) \times (\text{Earnings/Compensation}) \times (\text{Hours/Week}) \times (\text{GNP Deflator/CPI-W}) \times 52 \\ & = (\text{Real Earnings/Week}) \times 52. \end{aligned}$$

From this equation additional insight into increases in average real earnings can be obtained by analyzing increases in productivity and changes over time in each of the above linkages. Table 7A summarizes the average annual changes in each of these factors over the period 1954 to 1984. Tables 3 and 5 show historical levels and rates of increase in productivity and average real earnings for the U.S. economy.

Tables 7A, 7B, and 7C show that the decline in the growth of average real earnings has been the result of declines in the growth of productivity and declines in the linkages. The first linkage is the ratio of compensation to production. This ratio is calculated by dividing the total worker compensation in the U.S. economy by the Gross National Product. Compensation is measured by the Bureau of Economic Analysis (BEA) of the Department of Commerce and is reported in the National Income and Product Accounts (NIPA) as total employee compensation, for wage and salary workers, and as net proprietors income, for the self-employed. The method we use to subdivide GNP into the component attributed to wage and salary workers and that attributed to the self-employed is described in Section V.D.

Tables 25 and 25A through 25D provide a detailed presentation of the historical and projected values of the ratio of compensation to GNP. The ratio of compensation to production for wage and salary workers has dropped from 0.659 in 1954 to 0.639 in 1984, while the decline for the self-employed has been much greater—from 0.811 in 1954 to 0.591 in 1984. We assume some

continued decline in the ratio for wage and salary workers until a level of about 0.632 is attained in 1996. For the self-employed, a recovery in the ratio is assumed to occur to match the level of the wage and salary workers by 1996. After 1996, no change in this linkage is assumed to occur.

The second linkage is the ratio of earnings to compensation, which has had a depressing effect on the growth in average real earnings. For the self-employed, compensation and earnings are defined as being equal and thus no change in the ratio for the self-employed occurs. For wage and salary workers total employee compensation includes fringe benefits in addition to wages and salaries. The decline in the ratio of wages to compensation is the result of fringe benefits increasing at a faster rate than wages. Because fringe benefits offer both employers and employees many advantages, they can be expected to continue to grow faster than wages.

In many cases, fringe benefits are more desirable to employees than wages, because fringe benefits are often afforded better tax treatment and because they often provide, on a group basis, benefits that are either unavailable or much more expensive on an individual basis. Fringe benefits can also help employers to compete for new employees and to retain experienced ones. Therefore, more workers can be expected to be covered by fringe-benefit plans in the future, and most of those that are covered can expect an expansion in the types of benefits provided. In addition, the costs of many types of benefits, such as health insurance, pension plans, and Social insurance are rising faster than wages even without a liberalization in plan provisions. For all of these reasons, we believe that there is still much potential for continued faster growth in fringe benefits relative to wages.² The assumed ultimate rate of decline in this ratio was 0.1 percent, 0.2 percent, 0.3 percent, and 0.4 percent for alternatives I, II-A, II-B, and III, respectively, based on the present-law tax treatment of fringe benefits as of April, 1986.

The third linkage is the number of hours paid per week, which has also had a depressing effect on the growth in average real earnings over the past 30 years. In the analysis of the average number of hours paid per week, we used the figures published by the BLS in *Employment and Earnings* for "production or nonsupervisory workers on private nonagricultural payrolls" in the U.S. economy. Although this index does not cover the total U.S. economy (in particular, it excludes all self-employed), it is the only index currently available for periods back through 1951. Any error introduced into our historical analysis by assuming that this index applies for the total U.S. economy is reflected in the residual factor. The decline in the number of hours paid per week has been fairly steady over the last 30 years. Some of the factors contributing to this decline are the relative increase in young workers and female workers in the labor force (both groups work fewer hours than the average), the relative increase in employment of service industries versus manufacturing, and a desire by labor to work fewer hours (particularly when their average real earnings are increasing). We believe that this decline in the average number of hours paid per

¹Data considerations described in Section II.B.2. require analysis of average earnings per week for the U.S. economy.

²Wilkin, Gresch, and Glanz, "Growth in Fringe Benefits," Actuarial Note Number 113, Social Security Administration, Baltimore, MD, June 1982.

week will continue into the future, but at a slightly slower pace than in the past. We are assuming an ultimate annual rate of decline of 0.1, 0.2, 0.3, and 0.4 percent for alternatives I, II-A, II-B, and III, respectively (Table 7A).

The fourth linkage, referred to as "price adjustment," is the ratio of the GNP price deflator index to the Consumer Price Index for Urban Wage Earners and Clerical Workers (CPI-W). This linkage is necessary because productivity and real earnings are customarily expressed in constant, or real, dollars by dividing by the GNP price deflator and the CPI-W, respectively. Thus, an adjustment for the difference in these price indexes is necessary when comparing (real) productivity with real earnings. Although these two indexes may indicate different rates of price increase over relatively short periods, they tend to rise at about the same rate over an extended period. For this reason, we assume that these indexes will rise at essentially the same rate in the future.

A final factor which must be included in the historical analysis is the residual. It includes the errors due to any inconsistencies in the other linkages as well as any statistical discrepancies among the other figures. The residual amounts to a loss of 0.07 percent per year between average productivity and real earnings increases over the past 30 years (Table 7A). Future assumptions are, of course, assumed to include no error, and no statistical discrepancy, and thus the residual is assumed to be zero.

b. Average earnings in the U.S. economy versus average earnings for OASDI covered workers

Three factors contribute to the differences between our measures of average real earnings for the U.S. versus those for OASDI covered workers. First, over the years since the Social Security Act was passed in 1935, many changes in the types of work included in covered employment have been made. These changes have sometimes resulted in increases in the average covered earnings level relative to the level for the U.S. economy and have sometimes resulted in decreases. The second factor is the changing relative earnings levels of workers in different sectors, covered vs. noncovered, of the economy. These changes can cause average covered earnings to rise or fall relative to average U.S. earnings even when Social Security coverage is stable. Third, the fact that average earnings in the U.S. economy are actually calculated as average weekly earnings multiplied by 52 (see section II.B.2.) means that any change in the average number of weeks worked per year will cause a similar change in the level of average covered earnings relative to the level of U.S. earnings.

Over the past 30 years, average real covered earnings have increased at an average annual rate of 1.02 percent (Table 4A) compared with an average increase of 0.81 percent for U.S. earnings (Table 5A). We believe that most of this difference is attributable to changes in Social Security coverage and changes in relative earnings levels for different types of workers. We also believe that the impact of changes in the average weeks paid per year is less significant, partly because our efforts to quantify this factor have led us to estimates that vary widely (and even have opposite sign).

Because we have not as yet successfully quantified the three factors mentioned above, Table 8 compares changes in average earnings in the U.S. with changes in average covered earnings through two descriptive, if not necessarily explanatory, linkages. The first, the ratio of average weekly U.S. employed labor force to annual covered employment, has declined by 0.54 percent per year from 1954 to 1984 as Social Security coverage has been increased. The second, the ratio of total covered earnings to total U.S. earnings has increased at the rate of 0.75 percent per year over the same period for largely the same reason. Over the next 30 years, both of these trends are expected to continue for the OASDI program as Federal civilian employees hired after 1983 are included in the OASDI covered economy. However, we project the pace to slow considerably. Ultimately, by the year 2015, such changes in coverage are expected to be essentially complete, and thereafter the relative distribution of types of workers in the U.S. and the OASDI covered economies are assumed to stabilize. Average weeks worked per year is assumed to be stable after 1983. As a result, ultimate increases in average earnings are assumed to occur at essentially¹ the same rate in both the U.S. and OASDI covered economies. Because all federal civilian employees are included in the HI covered economy starting 1983, average HI covered earnings are expected to rise at essentially (the same rate as for the U.S. economy throughout the projection period.

3. Summary

Based on the direct analysis of expected future increases in average real covered earnings and the parallel analysis in relation to productivity, ultimate average annual real wage 'differentials' of 2.5 percent, 2.0 percent, 1.5 percent, and 1.0 percent were adopted for the 1986 Trustees Report assumptions, alternatives I, II-A, II-B, and III, respectively. Translated into compound annual real rates of growth, ultimate increases in average real wages were assumed to be 2.47 percent, 1.95 percent, 1.45 percent, and 0.96 percent, respectively. The corresponding ultimate compound real rates of growth in average covered earnings are 2.47 percent, 1.97 percent, 1.48 percent, and 0.99 percent, respectively. All of these ultimate rates apply to both OASDI (after 2015) and HI covered earnings (after 1995).

C. Price Indexes

Two price indexes play roles in our economic projections. These are the Consumer Price Index (CPI) and the GNP price deflator. Although these indexes measure price changes for different items, their growth rates over an extended period tend to be similar. The difference in the average annual increase in these indexes from 1954 to 1984 was only 0.08 percent (see "price adjustment" in Table 7B). For this reason, and because the CPI plays a more directly important role in the financial status of the OASDI program, we focus our analysis primarily on the CPI. Future rates of increase

¹Ultimately average self-employment income (SEI) is assumed to rise slightly faster than average wage and salary earnings in the U.S. economy. The assumed ultimate percentage of U.S. earnings that is covered is lower for SEI than for wages and salaries. The lower assumed rate of coverage for the self-employed who have a higher assumed rate of earnings increase depresses very slightly the assumed overall rate of earnings increase for all covered workers relative to the assumed rate of increase for all U.S. workers.

for the GNP price deflator are assumed to be essentially the same as those assumed for the CPI.

The CPI is a measure of the average change in prices over time in a fixed market basket of goods and services that people buy for day-to-day living. It has been published monthly since 1913 by the Bureau of Labor Statistics (BLS). In 1978, the BLS began publishing CPI's for two population groups: (1) a new CPI for all Urban Consumers (CPI-U), which covers approximately 80 percent of the total noninstitutionalized civilian population; and (2) a revised CPI for Urban Wage Earners and Clerical Workers (CPI-W), which represents about half the population covered by the CPI-U. Although the CPI-U is the index most often quoted by the BLS, the CPI-W is consistent with the CPI as it existed in 1972 when the Social Security automatic-adjustment provisions were enacted, and it is the index currently used to adjust Social Security benefits (see 20 CFR 404.272). Therefore, the CPI-W is the index projected in this study.

Beginning with January 1985, the BLS changed the way that homeowner costs are measured in the CPI-W to rental equivalence. This change was already made for the CPI-U as of January 1983. The rental-equivalence approach calculates homeowner costs on the basis of the estimated rent that owners would have to pay to rent the homes they own. The old method calculated homeowner costs on the basis of newly purchased homes and included the prices of homes, mortgage interest costs and property taxes, insurance, and maintenance and repair. The weights for home purchase and mortgage interest represented only persons who purchased homes in the base period. Although from the late 1960's through 1981, the rental-equivalence index generally rose more slowly than the old homeowner cost index, the opposite has been true more recently. We believe that the impact of this change on the CPI-W will be small enough so that analysis of past experience in the CPI-W will continue to be a valid basis for projecting future long-range trends.

Since 1913, the CPI has increased at an average annual rate of 3.3 percent. The annual increases have fluctuated widely between +17.4 percent in 1918 and -10.7 percent in 1921, making the detection and projection of trends difficult. In order to obtain a smoother time series, average annual increases over selected intervals have been calculated. These increases in the CPI are shown in Table 9A.

The 10-year moving average does a good job of smoothing out the fluctuations of the annual increases in the CPI. The 10-year average ending in 1985 of 7.04 percent is somewhat below the recent peak of 8.70 percent for the period ending 1982. However, this averaging also reveals that there has been a cyclical pattern of about 30 years duration. Thus, the 30-year moving average is a good choice in trying to discern whether or not there has been a long-range underlying trend in the CPI. This average shows a steady upward trend from 1.25 percent for the 30 years ending in 1951 to 4.70 percent for the 30 years ending in 1985. The decreases in the 10-year average experienced since 1982 may foretell a slowing and eventually a leveling off of the upward trend in the 30-year average. Incomplete figures for 1986 indicate that this may indeed be the case.

Of course, a numerical review of historical figures is only the first step in making projections for the future. Although the 30-year average increase in CPI has been steadily increasing since the end of World War II, we must look behind these trends and try to determine the underlying factors that have caused them. This is particularly the case when the factors that had a controlling effect in the past are not expected to do so in the future.

While past experience (as in the 1950's) has shown that restrictive fiscal and monetary policies are effective (although not perfect) tools for fighting inflation, these restrictive policies also result in an increase in unemployment. During "demand-pull" inflation, which occurs when demand exceeds the productive capacity of the economy, and when unemployment is low, restrictive policies can be applied relatively painlessly while effectively lowering inflation. These policies are less effective and certainly less desirable, however, in the face of "cost-push" inflation (as was experienced during the 1970's), when unemployment may already be high.

Of course, one of the purposes of government spending is to provide the public with needed income, goods, and services that would not otherwise be available. This obligation limits the government's ability to influence aggregate demand in the economy in order to optimize levels of employment and price inflation. The effectiveness of fiscal policy will always be tempered by competing social objectives.

The primary objective of monetary growth is to accomodate real economic growth, at least in the long-run. Recent experience has shown us that a tight monetary policy, while very effective at lowering demand and thus lowering inflation, also has a depressing effect on growth in real GNP. On the other hand, continued loose monetary policy results in unsustainable economic growth and inflation.

We see continued limitations on the government's ability to effectively regulate inflation in the future through fiscal and monetary policy. Moreover, problems such as large federal deficits and foreign debts held by U.S. banks will require continued consideration of accomodative monetary policies in the future with the consequent risk of higher inflation.

The effectiveness of the OPEC oil cartel in raising oil prices during the 1970's shows that "cost-push" inflation can be started by events outside of our country, and outside of our control. We should be aware that similar episodes of price hikes by foreign producers of various goods and materials could occur at any time with significant, and somewhat uncontrollable, effects on inflation. However, we do not believe that the impact of such occasional disturbances will be as great in the future, on average, as was the impact of oil prices during the 1970's. This point is especially well made by the low rate of inflation experienced since 1982, largely because of the decline in oil prices back to levels more consistent with those that prevailed prior to the price hikes of the 1970's.

The demographic shift in covered workers during the 1970's has already begun to turn around (see the preceding section on average earnings). The fiscal and monetary accomodation for the purpose of job creation that was warranted during the 1970's should be lessened in the future, thus reducing inflationary pressure.

In the past, inflation has not been a totally bad phenomenon. Its effects have been helpful to some. For example, prior to indexing of Federal income tax brackets, inflation resulted in continual increases in the average tax rate without any legislation allowing the Congress and the President to occasionally cut marginal tax rates and increase exemptions and still increase overall tax revenues as a percentage of national income. Also homeowners with fixed-rate mortgages saw the size of their monthly payments decline in real terms as inflation compounded. In the future, with indexed tax brackets, and variable-rate mortgages, which now comprise a significant proportion of new mortgages, these reasons for welcoming inflation will diminish greatly.

The future course of inflation is uncertain. Overall, factors which have driven inflation in the past and those we can foresee for the future seem to be balanced and thus suggest that neither extremely high nor extremely low rates of inflation will prevail. For the 1986 Trustees Report, the assumed ultimate rates of increases in CPI-W are 2.0 percent, 3.0 percent, 4.0 percent, and 5.0 percent for alternatives I, II-A, II-B, and III, respectively. The past and projected annual increases in the CPI-W are shown in Table 9B.

D. Unemployment Rate

Our aggregate projection method requires assumed future rates of unemployment for both the expected actual economy and the expected full-employment economy. The average method requires only projected actual rates.

1. Full-Employment

Full-employment unemployment rates are assumed to be fixed rates for each age-sex group, representing the lowest sustainable (noninflationary) rates of unemployment in a normally operating economy. The total full-employment unemployment rate (shown in Table 17) thus changes through time as the age-sex distribution of the labor force changes. From 1950 through 1980, the total full-employment rate rose from 4.2 percent to 4.8 percent. This rate is projected to decline from a level of 4.6 percent for 1984 to ultimate levels of 4.4 percent, 4.2 percent, 4.2 percent, and 4.0 percent for alternatives I, II-A, II-B, and III, respectively.

The reader may note that the assumed level of the total full-employment unemployment rates seem to be opposite to the optimistic vs. pessimistic concepts of the alternative sets of assumptions. For example, the ultimate full-employment unemployment rate is highest for alternative I (optimistic). This results from the high assumed birth rates for this alternative and the consequent higher concentration of younger persons in the labor force through the end of the 75-year projection period.

2. Actual

Since 1947, the actual unemployment rate has fluctuated between a low of 2.8 percent in 1953 and a high of 9.5 percent in 1982, as shown in Table 10A. Because the unemployment rate fluctuates widely with the business cycle, it is useful to average several years of data together. Table 10A also shows the average unemployment rate over selected intervals. The recent increases in the aggregate unemployment rate have had a strong influence on even the relatively long-range periods. For

example, the 15-year moving average, which was quite stable around 4.8 percent from 1961 through 1974, has since risen steadily to its current level of 6.8 percent for the period ending with 1984.

The recent high unemployment rates are the result, in part, of the changing age-sex composition of the labor force, the restructuring of the labor force to take advantage of improvements in technology, the extension of unemployment benefits, and the recently disappointing performance of the U.S. economy. A large part of the reason for the recently disappointing U.S. economic growth is the deterioration in our competitive position with foreign products resulting from trade barriers, health and safety regulations, and relatively high domestic labor costs.

The increase during the 1970's of the proportion of women and youth in the labor force has caused some of the increase in the aggregate unemployment rate because women and youth experience higher levels of unemployment than adult males. While the 15-year average unemployment rate (unadjusted) rose 2.1 percentage points from 4.7 to 6.8 percent in the period 1964 to 1984, the age-sex adjusted 15-year average rate rose only 1.6 percentage points—from 5.0 to 6.6 percent.

Many of the technological advances made over the past decade have resulted in new equipment and methods in the office and in the factory. Office automation and factory robotization have eliminated many clerical and blue-collar jobs, while creating many other jobs that require a higher level of technological training. This has made it necessary for the present labor force to retrain for new careers, leading to higher unemployment rates during the transition. Of course, the permanent loss of certain occupations and the creation of new ones is always a part of our dynamic economy, but the recent losses in such industries as automobiles and steel and gains in such industries as computers and telecommunications have been at historically fast rates due to both advances in technology and the need to modernize in order to meet foreign competition.

For some members of the labor force, the extension of unemployment benefits has served as a disincentive to seeking new employment. As mentioned before, the degree of poor performance of the economy during the 1970's must be viewed as atypical. To a large extent, it was the result of such factors as the oil and food price shocks, increased regulation, and rapid growth of the labor force. Although the future will not be free of periods of poor economic performance, future experience is expected to be better, on average, than that of the 1970's.

Based on consideration of these factors, average ultimate age-sex adjusted unemployment rates of 5.0, 5.5, 6.0, and 7.0 percent were selected for alternatives I, II-A, II-B, and III, respectively. The age-sex specific rates were determined based on their past relationship with the age-sex adjusted rate. Past and projected unemployment rates by age group and sex are shown in Tables 10E through 10H. The difference between full-employment and actual assumed ultimate aggregate unemployment rates is 0.4 percentage points, 0.9 percentage points, 1.3 percentage points, and 2.2 percentage points for alternatives I, II-A, II-B, and III, respectively, reflecting the different levels of optimism assumed (see Tables 17 and 18).

E. Labor Force Participation Rates

As with unemployment rates, our projection methods require both assumed actual and assumed full-employment rates of labor force participation.

1. Actual

As shown in Table 11C, from 1947 to 1984 the age-adjusted female labor-force-participation rate rose from 29.9 percent to 53.7 percent, a relative increase of about 80 percent. Because of this substantial increase, the overall age-sex-adjusted total labor-force-participation rate rose by about 15 percent, relatively, from 56.3 percent to 64.8 percent, during the period 1947-84, even while the age-adjusted labor-force-participation rate of males was dropping from 85.0 percent to 76.9 percent.

The decision to participate in the labor force depends upon many factors, including a person's marital status, the presence of a disabling condition, the state of the economy, the presence of children in the family, and for older workers, the availability and level of retirement benefits. We have compared the trend in the labor-force-participation rate for each age group and sex separately with the trend in each of these factors.

Since 1947, the labor-force participation of women has increased substantially at all ages except for ages 65 and over, with the largest increases being between ages 25 and 50. The increases have coincided with a decrease in the percentage of women who are married and a decrease in the number of children per woman. Except for alternative III, under which fertility rates are assumed to continue to decrease, both the percentage of women married and the number of children per woman are projected either to stay at about current levels or to increase. Therefore, these factors are not expected to continue pushing up participation rates for females to higher levels, as they have done in the past. The effect may actually be reversed. However, we believe that these factors account for only part of the recent increases and that such increases reflect fundamental changes in our society, especially with regard to the opportunities, rights, perceived abilities, and responsibilities of women. We expect this underlying trend to continue and have assumed that it will result in the labor-force-participation rates of women under age 55 being roughly 10 percentage points higher, by the year 2005, than they would be if only further changes in fertility and marital status were considered. Because recent increases in the labor-force-participation rates of the relatively young cohorts of women are likely to result in increased participation during the remainder of their working lifetimes, we believe that as these cohorts age, future increases in the labor-force-participation rates of relatively older women will be slightly higher than those of younger women.

The labor-force-participation rates of men declined between 1947 and 1984 for every age group, with the largest relative decreases occurring at the highest ages. The rates dropped by about 10 percent, relatively, for ages 25 through 54, but by about 20 percent, relatively, for ages 55 and over. The relatively small decreases for the prime working ages may be the result of the increasing competition from females and increased amounts of time necessary for retraining between jobs. The large decreases at the older ages occurred both because of these factors and because of the general

trend toward earlier retirement. This latter trend, which is also displayed in the participation rates of older females, has been facilitated by more prevalent and richer retirement and disability pension plans (including Social Security) and by increased personal savings.

In our projection for the future, we are not assuming any underlying trend in the participation rates of males between ages 25 and 45. For males age 45 and above we are assuming that a continuation of the recent trend toward earlier retirement along with a continuation in the trend toward longer periods of training between jobs will result in future participation rates that are a few percentage points lower than would be indicated by the other factors considered. Projected rates also reflect an increase in the labor-force participation of workers aged 62 and over beginning in the year 2000, because of the provision in the Social Security Amendments of 1983 that raises the normal retirement age from 65 to 67 during the period 2000 to 2022.

The past and projected labor-force-participation rates by age group, sex, and alternative are shown in Tables 11A through 11H. The total rate for all persons aged 16 and over is projected to change from 65.2 percent in 1985 to 64.2 percent, 59.0 percent, 57.9 percent, and 49.3 percent in 2060 for alternatives I, II-A, II-B, and III, respectively. Except for alternative I, the total rate decreases even though large increases are assumed for most of the age-specific rates for women. This results from the large increase in the portion of the population that is age 65 and over, where the rates are low. On an age-sex-adjusted basis, however, the rates increase significantly for three of the four alternatives: from 65.2 percent in 1985 to 68.7 percent, 67.5 percent, 66.4 percent, and 65.1 percent in 2060 for alternatives I, II-A, II-B, and III, respectively.

2. Full Employment

The relationship between full-employment and actual labor-force-participation rates is analyzed for past years in relation to differences between the full-employment and actual unemployment rates. Based on this relationship and assumed future rates of actual labor force participation, actual unemployment, and full-employment unemployment, the assumed aggregate rates of full-employment labor-force participation for the year 2060 are 64.3 percent, 59.3 percent, 58.3 percent, and 50.1 percent for alternatives I, II-A, II-B, and III, respectively (see Tables 17A through 17D). These rates exceed the assumed rates of actual aggregate labor force participation by 0.1 percentage points, 0.3 percentage points, 0.4 percentage points and 0.8 percentage points, for alternatives I, II-A, II-B, and III, respectively, reflecting the relative levels of optimism assumed.

F. Real Interest Rate

The assets held by the OASDI Trust Funds are generally invested in U.S. government securities. The rate of interest paid on the OASDI Trust Funds' investments plays a role in the future financial status of the program.

Over the 30-year period 1955 through 1984, the average of the annualized real interest rates for monthly new issues was 1.6 percent. For the purpose of analysis, those years can be split into four fairly distinct periods.

For 1955 through 1957, the average real rate was -0.1 percent; for 1958 through 1966, the average real rate was 2.0 percent; for the years 1967 through 1980, the average real rate was -0.1 percent; and for 1981 through 1984 the average real rate was 8.5 percent. We believe that future real interest rates will be somewhat higher, on average, than over the past 30 years, consistent with the assumed higher rate of growth in productivity (which presumes higher capital expenditures) and the likelihood of continued federal borrowing needs.

The ultimate assumed rates of real interest are 3.0 percent, 2.5 percent, 2.0 percent, and 1.5 percent for alternatives I, II-A, II-B, and III, respectively. Past and projected real interest rates are shown in Tables 12A, 12B, and 12C.

V. METHODS

Two separate tracks of development are utilized in order to interrelate all the various economic parameters necessary to make projections of the financial status of the OASDI (and the HI) program. These tracks, the aggregate method and the average method, were outlined and discussed in general terms in Section III.

The primary advantage of the aggregate method is that the development of actual GNP from the relatively smoothly growing potential GNP permits careful analysis of historical and possible future economic cycles. For more distant future periods when actual GNP is assumed to grow in tandem with potential GNP, consideration of cycles is unnecessary, and the average method becomes a more efficient means to the ultimate projection of effective taxable payroll.

Historically, the aggregate method has been the dominant approach for projecting economic parameters for the first 10 projection years. The aggregate method facilitates continuation of the current economic cycle and the transition toward a stable rate of economic growth, which is best measured by growth in real GNP. Continuation of economic projections for later years (when steady, average growth rates are assumed with no attempt to model business cycles) has historically been made with an emphasis on the average method. The relationship between potential and actual GNP is projected to stabilize soon after the tenth projection year and thus be of less significance for subsequent projections.

In the final analysis, neither track of development should be seen as fundamental, because for all projection years, the impact of each assumption is considered in the context of both methods, and the assumption or the method is adjusted when unreasonable or inconsistent projections result from either method. In this way, the two tracks of development become valuable checks on the accuracy and reasonableness of the overall results of our economic projections. We believe, however, that the aggregate method is more useful in preparing short-run projections, while the average method yields better dividends in the preparation of long-run projections.

The descriptions that follow in this section show how values for the derived economic parameters in both the aggregate and average methods are developed based on the assumptions for more basic parameters, which are described in Section IV.

A. Employment

The basic employment parameters that are utilized in our projections are the labor force and the employed labor force for the total U.S. economy and the covered workers, i.e., workers with any OASDI (or HI) taxable earnings at any time during the year, for the OASDI (or HI) covered economy. Labor force and employed labor force, on the other hand, actually reflect average weekly numbers for each year (see Section II.B.2.). This distinction is relevant when comparing numbers of covered workers to the employed labor force, as shown for the historical period in Table 16.

1. Labor Force and Employed Labor Force

The average (weekly) numbers of persons in the labor force (including the military both at home and abroad) for both full-employment and actual conditions are determined by multiplying the age-sex-specific labor-force-participation rates (Section IV.E.) by the corresponding numbers of persons in the U.S. noninstitutionalized population (Table 2). Past and projected labor force by age-group, sex, and alternative is shown in Tables 14A through 14G.

The average employed labor force for a year is computed for both full-employment and actual conditions by multiplying the total (average weekly) labor force by the complement of the total (average weekly) unemployment rate. Projections of total employed labor force are shown for full-employment and actual conditions in Tables 17 and 18, respectively.

2. Covered-Worker Rates

The projected covered worker rates for each year are calculated by age and sex with regression equations on the actual labor-force-participation rates and the age-sex-adjusted actual unemployment rate. The regression analyses are based on data for years 1964 through 1979, the last year for which complete data on covered workers were available. In the regression analyses, more weight is given to the more recent years so as to more accurately reflect the effect of several minor changes in coverage that have occurred since 1965 and to provide for a smoother junction between historical rates and projected rates. For example, the data for the starting year are given one-half of the weight given to data for the final year of 1979.

No additional parameter is introduced into the regression equations to specifically "explain" the fact that covered-worker rates relate to persons with any work during the year while labor force and unemployment are average weekly parameters because we assume that any trend from year to year in average weeks worked is likely to be highly inversely correlated with the trend in the unemployment rate, which is explicitly included in the regression.

Covered worker rates for future years were derived by applying regression equations to projected labor-force participation and unemployment rates. The results were adjusted to reflect coverage of federal civilian employees and employees of nonprofit organizations which were not included in historical data. Tables 13A through 13G show the past and projected OASDI covered-worker rates by age, sex, and alternative. HI covered worker rates are the same as for the OASDI program before 1983 and after 2014. Between 1983 and

2004, HI covered worker rates (not shown in this study) are slightly higher because all civilian federal employees are covered by the HI program beginning 1983, while this change in coverage occurs only gradually under the OASDI program, beginning in 1984 and reaching substantial completion by 2015.

3. Covered Workers

The average (annual) numbers of OASDI (and HI) covered workers for each year are determined by multiplying the age-sex-specific covered-worker rates by the corresponding numbers of persons in the Social Security area population (Table 1).

Past and projected numbers of OASDI covered workers by age group, sex, and alternative are shown in Tables 15A through 15G.

B. Average Real Earnings and Average Real Covered Earnings

Although average real earnings and average real covered earnings are shown as derived parameters in the outline of the average method (Section III.) projected values were selected based on both direct analysis of the historical series and development of the more basic parameters. A discussion of this method is presented in Section IV.B.

C. Potential (Real) GNP

When analyzing and projecting aggregate economic experience, we have found the basic concept of potential real GNP to be a very useful tool. This concept has the important characteristic of providing a smooth baseline series, which can be projected more easily than a series that fluctuates with economic cycles. Of course, the usefulness of potential real GNP goes beyond mere smoothness and ease of projection. Once the potential real GNP series is developed, the ratio of actual real GNP to potential real GNP is a readily understood measure, which reflects the position of the economy within the business cycle.

Table 17 shows estimated historical potential real GNP (in 1972 dollars). Estimates for years 1950 through 1980 were produced by the Council of Economic Advisors. Potential GNP is presented as the product of four factors. The first factor is the average full-employment employed labor force during the year, which is labeled "Employment" in the table. The second factor is the average level of real output per hour paid (or productivity) during the year for the full-employment employed labor force. The third factor is the average number of hours paid per week, as measured by the BLS for the total private nonfarm sector of the economy. The fourth factor is the 52 weeks in a year (see Section II.B.2.). For the historical data, the productivity factor was calculated as the residual. As such, this factor represents the average full-employment productivity for the entire U.S. economy, in contrast with the figures for the actual productivity shown in Table 3A.

For the purpose of projecting potential GNP, the assumed values for the four factors described above (see section IV. Assumptions) are combined. In order to make a meaningful projections of potential GNP for the years between 1984 (the last historical, estimated year) and 2015 (the beginning of the ultimate period during which the ultimate productivity assumption is assumed to prevail) a Cobb-Douglas production function is utilized.

In this function labor productivity is subdivided into the components of capital stock, energy, and research and development stock. Future values for these factors are selected to reflect recent past experience and are assumed to trend so that convergence to the ultimate productivity increase assumption is achieved by 2015.

Projections of potential real GNP by the aggregate method are summarized in Tables 17A through 17D.

D. Actual Real GNP

For the first few years of the projection, percentage rates of change in actual real GNP are postulated by calendar quarter for each alternative, taking into account the current status of the economy within the business cycle and the plausible change in this status which is consistent with the outlook for that alternative. For 1986, the resulting ratios of actual GNP to potential GNP ranged from 96.1 percent for alternative I to 95.2 percent for alternative III. Since 1950, this ratio has fluctuated between 103.1 percent (in 1951) and 90.5 percent (in 1982), averaging about 98 percent. When the economy is operating at its deemed full-employment level, the actual-to-potential ratio is by definition 100 percent. Regression analysis of age-sex-specific unemployment rates on the actual-to-potential ratio shows that ratios of 99.2 percent, 98.3 percent, 97.3 percent, and 95.5 percent correspond to the ultimate age-sex-adjusted unemployment rates of 5.0 percent, 5.5 percent, 6.0 percent, and 7.0 percent assumed for alternatives I, II-A, II-B, and III, respectively. After extending the current economic cycle through about 1988, actual real GNP is assumed to grow at an annual rate of 4.0 percent, 3.5 percent, and 3.0 percent for alternatives I, II-A, and II-B respectively, until the ratio of actual to potential GNP reaches its ultimate level during 1991 or 1992. For alternative III, a second economic cycle is modeled through 1991, after which a steady growth rate of 2.2 percent is assumed for actual real GNP until the ultimate ratio of actual to potential GNP is achieved for 1995. Once the ultimate actual to potential GNP ratio is obtained, actual GNP is assumed to increase at same rate as potential GNP.

For each alternative, projected nominal GNP is obtained by multiplying the real GNP by the projected GNP implicit price deflator. The deflator is assumed to increase at the same rate as the CPI during the projection period.

Tables 18 and 18A through 18D show the employment, productivity, and hours per week that correspond with the actual GNP. The actual employment for projection years prior to reaching ultimate values is obtained by first deriving the actual unemployment rates from the ratio of actual to potential GNP using an historically-based regression equation. Then actual labor-force-participation rates are projected in relation to full-employment participation rates, based on the relationship between projected actual and potential GNP, again using historically-based regression equations. Finally, the actual participation rates and unemployment rates are applied to the noninstitutionalized U.S. population to determine the projected actual level of employment. Average hours paid per week are projected as described in Section IV.B.2. and are assumed to be the same as for full-employment conditions.

Average weeks per year are assumed constant at 52 (see Section II.B.2.). Productivity rates shown in these tables are calculated as the residual and thus show some year-by-year variation although, over the ultimate period 2015 through 2060, the average rate of increase is, of course, consistent with the assumed values discussed on Section IV.A. The residually-determined values for actual productivity for historical years do not exactly match those computed based on BLS data for the total economy, because of the simplified representation of changes in hours worked adopted for these tables.

We have separated GNP into components attributable to the work of wage and salary workers and to the work of proprietors and partners. These separate values are shown in Tables 19 and 19A through 19D. Separate components of GNP are necessary for separate historical analysis of productivity for the wage and salary workers and for the self-employed workers, as discussed in Section IV.A.

E. Effective Taxable Payroll

Effective taxable payroll reflects covered earnings of wage and salary workers and self-employed workers, plus deemed military service wage credits for both the OASDI and HI programs. For HI effective taxable payroll only, taxable earnings of railroad workers are also included. Railroad earnings are reflected in OASDI program financial estimates through the net railroad transfer which is included as a separate component of the total estimated income for the program.

The relatively small effects of deemed military service wage credits for years 1984 and later (between \$3 billion and \$4 billion per year) are projected assuming a small increase in the number of uniformed military through 1995 with no increase thereafter. The larger effect for 1983 (\$61 billion) is based on the transfer which accounted for much of the deemed credits for earlier years when deemed credits were not reflected in effective taxable payroll. These deemed military service wage credits are added to the projections of effective taxable payroll based on covered earnings, which are described in the balance of this section. Projected values for deemed military wage credits and railroad effective taxable payroll are shown in Table 24. Historical and projected values for effective taxable payroll are shown in Table 21 for the OASDI program and in Table 23 for the HI program. It should be noted that figures shown for HI effective taxable payroll through the year 2010 represent official estimates used for the HI Trustees Report. Because explicit values for HI effective taxable payroll were not used for years after 2010, the values shown in Table 23 are presented for illustrative purposes only.

1. Aggregate Method

Projection of effective taxable payroll under the aggregate method is accomplished by analyzing several linkages between GNP and effective taxable payroll. These include the ratios of compensation to GNP, earnings to compensation, OASDI covered earnings to earnings, and OASDI taxable earnings to covered earnings. Historical values for these ratios of linkages are shown in Table 20; projected values are shown in Tables 20A through 20D, for the OASDI program and in Tables 22A through 22D for the HI program. These

linkages are the analog to the linkages between productivity and average covered earnings analyzed for the average method.

a. Wage and Salary Workers

In the analysis of the effective taxable wages it is useful to start with total employee compensation—that is, the employees' share of the total value of production in the U.S.. The ratio of employee compensation to GNP rose from 55 percent in 1951 to 58 percent in 1961, and to 60.7 percent in 1970. Since 1969, this ratio has generally remained between 59 and 61 percent. Much of the past growth in this ratio appears to be the result of a shift in the percentage of GNP attributable to wage and salary workers (as opposed to that portion of GNP attributable to self-employed workers) from 84 percent of GNP in 1951 to 93 percent of GNP in 1984. For this reason, and because we assume that the percent of GNP that is attributable to wage and salary workers will stabilize in the future, we do not anticipate any long-range trend away from the current ratio of employee compensation to total GNP. Therefore, we are projecting this ratio to remain essentially between 59 and 60 percent during the long-range projection period for all four alternatives.

Because only the wage portion of employee compensation is subject to taxation, it is useful to analyze the ratio of wages to compensation. This ratio has declined fairly steadily over the last 30 years at an average annual rate of 0.4 percent. This means that other forms of compensation, generally referred to as fringe benefits, have been growing faster than wages. Of course, for our purposes the term 'fringe benefits' refers only to that portion of total compensation not subject to Social Security taxes, such as employer contributions for group insurance and pension plans. Cash items, such as vacation pay, which are treated as a continuation of wages and are taxed, are not included in fringe benefits. The average annual rates of change in this ratio were analyzed in the real-earnings section (IV.B.2.). The ultimate rate of decline in the ratio of wages to employee compensation is assumed to be 0.1 percent, 0.2 percent, 0.3 percent, and 0.4 percent for alternatives I, II-A, II-B, and III, respectively.

Not all wages in the U.S. economy are paid for employment that is covered by the OASDI (OSHI) program, and vice versa. Therefore, it is necessary to analyze the ratio of covered wages to total wages. This ratio is highly dependent upon the types of employment that the law specifies as being covered. This ratio rose from 77 percent in 1951 to 87 percent in 1960, as a result of the expanded coverage provided by several laws enacted during the 1950's. The most significant new groups were farm and domestic workers and the armed forces. Coverage was also expanded several times during the 1960's and 1970's, although to much less significant types of employment, so that the ratio of OASDI covered wages to total wages increased to 88.1 percent in 1970 and to 91.4 percent in 1984. These increases occurred even while some State and local governments dropped their coverage under Social Security. The ratio of HI covered wages to total wages rose to 95 percent, in 1983, in which year all federal civilian employees became covered under the HI program.

Future increases in the ratio of OASDI covered wages to total wages can be expected as a result of the enactment of the Social Security Amendments of 1983. This law makes coverage of all newly hired civilian Federal employees mandatory after 1983. In addition, it prohibits State and local governments from withdrawing their coverage in the future. We assumed that both OASDI and HI covered wages will increase to about 96 percent of total wages after the turn of the century for all four alternatives.

Covered wages above the contribution and benefit base (earnings base) are not taxed (except for the employer tax on excess multiple-employer wages). Therefore, it is necessary to analyze the ratio of taxable wages to covered wages. In the distant past, when there were only infrequent ad hoc increases in the earnings base, this ratio tended to drift downward as the wages increased and then to spike up in the year of an earnings-base increase. Since the earnings base has been indexed to increase automatically with average U.S. wages, this ratio has become more stable. The automatic-adjustment provision of present law should keep this ratio fairly stable in the future. Therefore, the ratio of taxable wages to covered wages is assumed to remain between 91 and 92 percent in the future for all four alternatives.

Taxable wages include all wages subject to FICA tax. In general, employers and employees are each taxed on these wages. However, there are two major exceptions. Only the employee tax is applied to tips representing remuneration above the Federal minimum-wage level and only the employer tax is applied to "multiple-employer excess wages." Multiple-employer excess wages occur when an employee receives wages from more than one employer during a calendar year and the combined wages exceed the maximum taxable earnings base. During the year, each employer will remit taxes for both himself and the employee up to the maximum taxable amount, independently of any wages paid to the employee by another employer. After the end of the year, the employee can file to receive a refund on any taxes withheld from pay and remitted for him that are in excess of the total taxes payable for a single job at maximum taxable earnings, while the employers receive no such refund.

Taxable wages on which the employee tax is applied are referred to as employee taxable wages. These include all declared tips and exclude multiple-employer excess wages. Taxable wages on which the employer tax is applied are referred to as employer taxable wages. This include multiple-employer excess wages and exclude tips representing remuneration above the minimum wage level (but include implied tips, to the extent necessary, so that the sum of tips and wages are at least equal to the minimum hourly wage). The ratios of employee taxable wages to taxable wages and employer taxable wages to taxable wages are both just under 1.0. The employer wages are higher than the employee taxable wages because the total amount of employer 'excess wages' at the current earnings base is larger than the total amount of tips in excess of the Federal minimum wage. Effective taxable wages are the average of the employee taxable wages and the employer taxable wages.

b. Self-Employed Workers

When analyzing the relationship between GNP and effective taxable self-employment income, essentially the same method is used as is used for wages. For the self-employed, compensation is defined as self-employment income for the U.S. economy (referred to as 'net proprietors income' in the National Income and Product Accounts developed by BEA of the Department of Commerce). The ratio of self-employment income to total GNP has declined from 13 percent in 1951 to 4.2 percent in 1984, while the proportion of total GNP that is attributable to the self-employed dropped from 16 percent to 7 percent.

Much of the drop in the ratio of self-employment income to total GNP has been in net farm income which was 5 percent of GNP in 1951 but less than 1 percent in 1984. Obviously, there is not much more room for farm income to decrease relative to GNP. Meanwhile, nonfarm net proprietors income dropped from 8 percent of GNP in 1951 to 3 percent in 1984. A large portion of this drop is probably the result of the increased formation and incorporation of partnerships, especially in the legal and medical professions. Each of these factors has led to the reduction of both self-employment income and GNP attributable to the self-employed.

Another major factor in the decline in the ratio of self-employment income to total GNP is the decline in self-employment income as a percentage of that portion of the GNP attributable to the self-employed, from over 80 percent in 1951 to less than 60 percent in 1984. Incorporation of many established businesses and the increase in the number of newly self-employed workers resulting from layoffs and plant closings over the past 15 years have driven this decline. We do not believe that these factors will continue at the same pace in the future.

The ratio of self-employment income to total GNP is projected to continue to decrease by a small amount for 10 more years and then to stabilize at about 3.6 percent for all four alternatives. Similarly, the ratio of self-employment GNP to total GNP is projected to decline slightly to an ultimate level of about 5.7 percent. However, the decline in the ratio of self-employment income to that portion of the GNP attributed to the self-employed is projected to turn around, ultimately reaching levels between 63 percent and 64 percent for all four alternatives.

Much self-employment income for the U.S. economy is not covered. For example, if a worker's self-employment income is less than \$400 in a calendar year, then none of this income is covered. The ratio of covered self-employment income to total U.S. self-employment income has increased in the past as more types of self-employment income have become covered. This ratio is likely to decrease slightly for a while, however, because farm income, which is covered less than nonfarm income, is likely to become a larger share of total self-employment income. The coverage ratio for self-employment income may seem lower than expected, based on the coverage provisions of the Social Security law. This results largely from discrepancies between how farm income is determined for the national income accounts and how it is determined for Social Security.

This ratio is projected to drop from around 80 percent in 1984 to ultimate values reached in 1994 ranging from 71.6 percent for alternative I to 71.3 percent for alternative III.

Just as with wages, covered self-employment income above the earnings base is not taxable. The ratio of taxable self-employment income to covered self-employment income has fluctuated in the past in a pattern similar to that of the ratio of taxable wages to covered wages. In years when the earnings base remained the same, the ratio has fallen. The taxable to covered ratio for self-employment income is lower than the corresponding ratio for wages, reflecting the higher average earnings of the self-employed. The ratio of taxable to covered self-employment income has tended to rise gradually even in years when the earnings base has increased automatically, reflecting the slower rate of increase in average self-employment income than in average wages. We are projecting this trend to continue until 1994, resulting in the ratio of taxable to covered self-employment income rising from 79 percent in 1984 to ultimate values ranging from 87 percent for alternative I to 85 percent for alternative III.

The reader may note that projected values for HI taxable self-employment income are lower than those for OASDI after 1995. This occurs because there was not time during development of the 1986 Trustees Reports to incorporate an improved method in the OASDI projection. This improvement, which was included in HI projections reflects the fact that average SE income is projected to rise faster than average wages, and thus faster than the taxable maximum. The result is to decrease the ratio of HI taxable self-employment income to self-employment income after 1995. This change will also be incorporated in future OASDI projections.

Prior to 1984, it was necessary to multiply taxable self-employment income by the ratio (tax rate on self-employment income)/(combined employee-employer tax rate) to obtain effective taxable self-employment income. This adjustment is not needed after 1983 since the tax rate on taxable self-employment income is now equal to the combined employer-employee tax rate for both programs. Therefore, taxable self-employment income and effective taxable self-employment income are equivalent after 1983.

c. Summary

As a result of all of these assumptions, the ratio of effective taxable payroll to GNP is projected to decrease gradually over the long-range future from 44 percent in 1984 (45 percent for HI) to values in 2060 of about 43 percent, 40 percent, 37 percent, and 34 percent for alternatives I, II-A, II-B, and III, respectively. Of the linkages between GNP and effective taxable payroll, the ratio of wages to compensation is assumed to have the most powerful long-range effect.

During the short-range period (1985-95), effective taxable payroll is estimated from GNP by a detailed method involving the interrelationships between the two. The projection of these interrelationships and the calculation of effective taxable payroll are performed under the direction of Mr. Kenneth G. Sander of the Office of Research, Statistics, and International Policy, Social Security Administration.. The ratios of effective

taxable payroll to GNP in 1985 through 1995 shown in Tables 20 and 22 summarize the results of Mr. Sander's projection.

2. Average Method

Projection of effective taxable payroll by the average method makes use of assumed increases in average real covered earnings (Section IV.B.) and projected numbers of workers in covered employment (Section V.A.). Total amounts of taxable wages for employees and employers, and the total amount of taxable self-employment income that are projected by Mr. Sander (see subsection covering aggregate method) for 1995, are increased by the combination of projected increases in the number of covered workers and assumed increases in average covered wages and average covered self-employment income, respectively. Adjustment to reflect the minor change in ratios of taxable earnings to covered earnings between projected values which are attained in 1995 and the projected ultimate values for 1996 (these ratios are also used in the aggregate method and are discussed in the prior subsection) yields projected taxable payroll for employers, employees, and the self-employed. The amount of deemed military service wage credits and the railroad taxable payroll are projected as described earlier in this section. Finally, projected effective taxable payroll is computed as the sum of each of these totals multiplied by the employee, employer, or self-employed tax rate, as appropriate and divided by the combined employee, employer tax rate.

VI. RESULTS

Over the past 30 years, the total U.S. labor force has increased at an average annual rate of 1.8 percent, reflecting both the increasing population due to high birth rates experienced until the early 1970's and the rapid rise in labor-force-participation rates of women. The combination of very low birth rates since 1970, expected future birth rates far below the high levels experienced during the 1940's and 1950's, and the expected leveling off of female labor-force-participation rates by about the turn of the century result in projected average annual rates of growth in total U.S. labor force between 1984 and 2060 of 0.68 percent, 0.35 percent, 0.33 percent, and -0.15 percent for alternatives I, II-A, II-B, and III, respectively.

The impact that the slower future growth in the total U.S. labor force will have on the rate of growth in real GNP is expected to be partially offset by (1) higher future productivity increases for all but the pessimistic assumptions (alternative III) than experienced over the past 30 years (reflecting, in part, the maturing of the labor force after 1984), and (2) the expected return to lower unemployment rates (compared with the 1984 level), which is in contrast to the trend toward higher unemployment rates over the past 30 years. The resulting projected average annual increases in real GNP are 3.18 percent, 2.44 percent, 2.03 percent, and 1.11 percent over the period 1984 to 2060 based on alternatives I, II-A, II-B, and III, respectively, in contrast with the average annual increase of 3.32 percent experienced between 1954 and 1984. Thus in aggregate terms, annual rates of real growth in GNP are expected to be less, on average, in the future than over the past 30 years for all but the optimistic assumptions (alternative I).

However, when analyzed in terms of per capita real GNP (defined as total GNP divided by the total number of persons in the U.S. population), we see that the experience of the past 30 years, during which the average annual growth rate was 2.10 percent, is close to the projected rate for the intermediate (alternative II-A) assumptions and is roughly in the center of the projected average annual growth rates of 2.48 percent, 2.02 percent, 1.61 percent, and 1.04 percent for the period 1984 through 2060 for alternatives I, II-A, II-B, and III, respectively.

As is the case with the labor force, the projected average annual rates of increase in the number of OASDI covered workers between 1984 and 2060 is less for each alternative (0.72 percent, 0.39 percent, 0.36 percent, and -0.12 percent for alternatives I, II-A, II-B,

and III, respectively) than the average annual rate of 2.32 percent experienced between 1954 and 1984. Both historical and future rates of increase in OASDI covered workers are slightly higher than corresponding increases in labor force because of the trend toward coverage of an increasing proportion of all workers.

The combination of the slower future rate of growth in the number of workers and the slowdown in the trend toward increased coverage under the OASDI program results in projected average annual rates of increase in real effective taxable payroll (3.2 percent, 2.3 percent, 1.8 percent, and 0.8 percent for alternatives I, II-A, II-B, and III, respectively between 1984 and 2060) that are lower than the average annual growth rate of 4.0 percent experienced between 1954 and 1984.

Table 1A: Male Population in the Social Security Area by Age Group on July 1, 1947-1984 (in thousands)

| Year | Age Group | | | | | | | | | | | Total (16+) | |
|------|-----------|--------|--------|--------|-------|-------|-------|-------|-------|-------|-------|----------------|--------|
| | 16-19 | 20-24 | 25-29 | 30-34 | 35-39 | 40-44 | 45-49 | 50-54 | 55-59 | 60-64 | 65-69 | 70+ | |
| 1947 | 4474. | 5971. | 6488. | 5983. | 5760. | 5250. | 4833. | 4230. | 3618. | 3000. | 2236. | 3188. | 55031. |
| 1948 | 4530. | 5988. | 6539. | 6044. | 5872. | 5334. | 4853. | 4261. | 3690. | 3071. | 2285. | 3289. | 55754. |
| 1949 | 4450. | 5937. | 6589. | 6118. | 6004. | 5429. | 4882. | 4299. | 3773. | 3152. | 2346. | 3407. | 56386. |
| 1950 | 4351. | 5931. | 6629. | 6203. | 6130. | 5532. | 4922. | 4333. | 3838. | 3199. | 2430. | 3517. | 57016. |
| 1951 | 4340. | 5629. | 6579. | 6334. | 6235. | 5642. | 5037. | 4387. | 3929. | 3268. | 2494. | 3647. | 57522. |
| 1952 | 4318. | 5251. | 6498. | 6432. | 6277. | 5717. | 5140. | 4400. | 3964. | 3323. | 2555. | 3762. | 57638. |
| 1953 | 4347. | 5091. | 6462. | 6448. | 6289. | 5773. | 5226. | 4442. | 3975. | 3392. | 2611. | 3883. | 57939. |
| 1954 | 4431. | 5006. | 6389. | 6553. | 6296. | 5837. | 5328. | 4497. | 4002. | 3453. | 2668. | 4016. | 58476. |
| 1955 | 4605. | 5700. | 6491. | 6697. | 6447. | 5924. | 5439. | 4552. | 4049. | 3501. | 2716. | 4155. | 60274. |
| 1956 | 4695. | 5635. | 6431. | 6664. | 6541. | 5985. | 5514. | 4625. | 4096. | 3544. | 2756. | 4276. | 60762. |
| 1957 | 4846. | 5621. | 6322. | 6609. | 6635. | 6044. | 5594. | 4720. | 4134. | 3559. | 2809. | 4397. | 61290. |
| 1958 | 5031. | 5695. | 6163. | 6584. | 6656. | 6092. | 5669. | 4802. | 4203. | 3550. | 2876. | 4516. | 61838. |
| 1959 | 5384. | 5806. | 6031. | 6502. | 6708. | 6125. | 5732. | 4890. | 4284. | 3559. | 2950. | 4639. | 62610. |
| 1960 | 5836. | 6030. | 5886. | 6320. | 6493. | 6009. | 5624. | 5063. | 4199. | 3586. | 2995. | 4629. | 62667. |
| 1961 | 6001. | 6204. | 5856. | 6253. | 6508. | 6099. | 5668. | 5153. | 4286. | 3603. | 3042. | 4757. | 63432. |
| 1962 | 6069. | 6443. | 5854. | 6180. | 6494. | 6201. | 5711. | 5226. | 4401. | 3629. | 3037. | 4867. | 64112. |
| 1963 | 6491. | 6830. | 5912. | 6087. | 6449. | 6299. | 5750. | 5281. | 4517. | 3655. | 3025. | 4963. | 65259. |
| 1964 | 6861. | 7111. | 6010. | 5987. | 6387. | 6373. | 5800. | 5332. | 4630. | 3700. | 3024. | 5061. | 66276. |
| 1965 | 7249. | 7360. | 6099. | 5933. | 6313. | 6411. | 5864. | 5376. | 4723. | 3757. | 3033. | 5143. | 67261. |
| 1966 | 7651. | 7509. | 6272. | 5903. | 6241. | 6424. | 5949. | 5419. | 4804. | 3836. | 3043. | 5210. | 68261. |
| 1967 | 7565. | 8110. | 6505. | 5898. | 6165. | 6409. | 6050. | 5459. | 4869. | 3938. | 3061. | 5281. | 69308. |
| 1968 | 7673. | 8372. | 6886. | 5958. | 6074. | 6370. | 6151. | 5499. | 4924. | 4050. | 3084. | 5335. | 70376. |
| 1969 | 7831. | 8724. | 7154. | 6055. | 5977. | 6312. | 6226. | 5547. | 4969. | 4148. | 3116. | 5387. | 71448. |
| 1970 | 8048. | 9109. | 7443. | 6187. | 5967. | 6280. | 6287. | 5621. | 5018. | 4239. | 3150. | 5457. | 72805. |
| 1971 | 8242. | 9593. | 7597. | 6345. | 5938. | 6215. | 6271. | 5727. | 5050. | 4320. | 3216. | 5532. | 74045. |
| 1972 | 8412. | 9588. | 8219. | 6577. | 5944. | 6138. | 6210. | 5862. | 5071. | 4414. | 3312. | 5573. | 75322. |
| 1973 | 8612. | 9778. | 8500. | 6964. | 5993. | 6050. | 6176. | 5951. | 5100. | 4482. | 3407. | 5632. | 76643. |
| 1974 | 8769. | 10017. | 8869. | 7244. | 6075. | 5961. | 6120. | 6005. | 5161. | 4550. | 3498. | 5729. | 77997. |
| 1975 | 8885. | 10309. | 9260. | 7484. | 6161. | 5868. | 6091. | 6009. | 5280. | 4571. | 3614. | 5838. | 79369. |
| 1976 | 8967. | 10547. | 9748. | 7627. | 6312. | 5839. | 6031. | 6003. | 5394. | 4620. | 3696. | 5949. | 80732. |
| 1977 | 9000. | 10815. | 9729. | 8242. | 6534. | 5851. | 5958. | 5955. | 5537. | 4668. | 3777. | 6075. | 82141. |
| 1978 | 8996. | 11044. | 9917. | 8529. | 6917. | 5912. | 5881. | 5939. | 5643. | 4725. | 3843. | 6219. | 83565. |
| 1979 | 8968. | 11228. | 10157. | 8893. | 7195. | 6005. | 5804. | 5906. | 5708. | 4787. | 3911. | 6394. | 84957. |

NOTE: 1) FULL-EMPLOYMENT REFLECTS THE ASSUMED MAXIMUM SUSTAINABLE LEVEL OF ECONOMIC GROWTH.

2) EMPLOYMENT IS THE AVERAGE WEEKLY EMPLOYED LABOR FORCE DURING THE YEAR.

3) POTENTIAL GNP IS CALCULATED AS THE PRODUCT OF THE FULL-EMPLOYMENT VALUES OF EMPLOYMENT, PRODUCTIVITY, HOURS PER WEEK, AND A VALUE OF 52 WEEKS PER YEAR.

NOTE: 1) FULL-EMPLOYMENT REFLECTS THE ASSUMED MAXIMUM SUSTAINABLE LEVEL OF ECONOMIC GROWTH.
 2) EMPLOYMENT IS THE AVERAGE WEEKLY EMPLOYED LABOR FORCE DURING THE YEAR.
 3) POTENTIAL GNP IS CALCULATED AS THE PRODUCT OF THE FULL-EMPLOYMENT VALUES OF EMPLOYMENT, PRODUCTIVITY, HOURS PER WEEK, AND A VALUE OF 52 WEEKS PER YEAR.
